A child, aged 3 years, was admitted to the Belfast Hospital for Sick Children on June 5, 1937, with a history that he had swallowed granules of digitalin (nativelle). The evidence pointed to his having consumed twelve tablets, each 1/600 grain (totalling 1/50 grain of digitalin), at 9.30 a.m. on the previous day. He refused his dinner at 1.30 p.m., and in about two hours began to vomit and have loose motions. He had been subject to attacks of "acidosis," and consequently the gastro-intestinal irritation was not associated with the consumption of the granules; the mother thought she had made him spit out all the granules when she first discovered that he had been in possession of the bottle. Nothing apart from the vomiting and diarrhoea was noticed until 7.30 a.m. on the day of admission, when his mother noted that the pulse was slow. He was seen by his doctor and admission to hospital advised.

On admission irregular systoles were noted, but there were no enlargement of the heart or murmurs. The average pulse rate was 84. There was some incontinence of urine. He was given 1/64 grain of strychnine hydrochloride and hourly records of the pulse rate were made. The record showed that by 6 p.m. the rate was 100, and this was maintained until midnight, then there occurred a gradual fall, until at 9 a.m. on June 6 the rate was 52. The strychnine was repeated, and the rate increased within an hour to 80, and at 11 p.m. atropine sulphate, 1/100 grain, was given. The result of the atropine was to raise the rate to 98 at 1 a.m. There was a steady fall from this level until at 7 a.m. it was 60, when the strychnine and atropine were repeated, the rate rising to 88 within an hour, falling to 70 at midday, and rising again to 90 at 3 p.m. This rate was maintained with some consistency until evening, when a fall to 54 began, starting at 8 p.m. At midnight 2 ccm of caffeine sodium benzoate were given, but by 2 a.m. the rate had not increased, and the strychnine-atropine was administered with the result of a rapid rise to 88 within two hours. The pulse rate did not give any cause for further alarm and in a few days registered 66 to 70 treatment being discontinued. Unfortunately an electrocardiogram was not taken on admission, but one taken on the third day did not show any abnormality of rhythm.

The after history is that the boy has remained without any ill effects. He had an attack of pneumonia in October, 1937, and of measles in January, 1938. He has been singularly free from attacks of "acidosis" since his experience.

## Reviews

### CHRONIC RHEUMATIC DISEASES

*A Survey of Chronic Rheumatic Diseases* Contributed by contemporary authorities in commemoration of the Bicentenary of the Royal National Hospital for Rheumatic Diseases Bath 1738-1938. Compiled under the direction of the following Editorial Committee: R G Gordon (Chairman), G P R Aldred-Brown, J Barnes Burt, F J Poynton, R Waterhouse, G D Kersley (Pp 338, illustrated 18s net) London, New York, Toronto Humphrey Milford, Oxford University Press 1938

Rheumatism has bulked large in the news these last weeks as the International Congress on Rheumatism and Hydrology has followed the course of earlier invaders of this country from London up the Thames valley to Oxford, and thence to the warm springs of Bath. Whether by chance or design, their visit coincides with the bicentenary of the Royal Mineral Water Hospital at Bath, which is commemorated in a more formal and permanent manner by *A Survey of Chronic Rheumatic Diseases* contributed by contemporary authorities and edited by a committee of Bath physicians. Here are more than a score of essays on the history, aetiology, morbid anatomy and physiology, classification, and treatment of the rheumatic diseases. The general lines of classification and the clear cut distinction of rheumatoid arthritis, osteoarthritis, and gout are now universally accepted. Indeed, it is probable that separation has been almost too complete, neglecting the links that bind these diseases together and the occasions when one is succeeded by or associated with another. Dr Poynton concludes that the rheumatisms are more allied to one another than to any other disease, and are a family group among diseases due to a common weakness. "Is it not possible that we may be born with weak connective tissue in which the cells are of poor quality, and that these react feebly to the causes of rheumatism?"

The editorial committee has done its work well, and has produced more than a mere *Festschrift*, for the book gives a complete account of the rheumatic diseases. Professor Aschoff shows how little we know of pathology in general and of rheumatism in particular when we describe these diseases as allergic. Allergy plays no part either in osteoarthritis, which involves essentially mechanical or metabolic factors in the widest sense, or in rheumatoid diseases arising from specific or non-specific infections. Acute rheumatism, like tuberculosis and syphilis, may enter into an allergic phase, but the therapy of the physician must be directed against the infection. After a summary of the arguments for and against the infectious theory of rheumatoid arthritis, documented with 175 references, Dr Hench comes down so faint-heartedly on the side of microbial origin as almost to damn the infectious theory. It would appear from this survey that we can recognize the manifestations of the different rheumatic diseases with great accuracy and we can relieve their symptoms, but we know little of the aetiological factors and their relative importance, and we have scant power to influence the underlying disease process. The most enthusiastic supporters of gold treatment cannot deny that many cases of ankylosing spondylitis and of rheumatoid arthritis in the florid stage are resistant to treatment. It may be that we await some entirely fresh conception of the rheumatic diseases which will put infection in a secondary role, in the same way that conditioned deficiency has replaced haemolysis as the essential fault in pernicious anaemia. The remissions of rheumatoid arthritis with jaundice, and to a less extent with pregnancy, show that inflammatory changes in joints

can improve remarkably when the internal environment of the organism is altered. The acute attack of gout is associated with all the local signs of inflammation—heat, redness, oedema and polynuclear exudation—and with general disturbances such as increase in the erythrocyte sedimentation rate yet all these phenomena can be satisfactorily explained by the accumulation of uric acid in the blood and its deposition as sodium biurate in the tissues. In the pursuit of infection as the culprit in rheumatoid arthritis we may be following the wrong trail.

In what other ways can the aetiology of the rheumatic diseases be attacked? It is notorious that certain forms of rheumatism are associated with or affected by damp climates but there is need for many more data on their geographical distribution, their occupational incidence, and their relation to changes in weather. Our English climate changes too rapidly for us to correlate the incidence and severity of rheumatism with the hot and cold fronts of air masses which accompany the passage of cyclonic disturbances but within our Empire every range of climate is available for field observations. Dr Godfrey reports to the International League against Rheumatism that he has never seen a true case of rheumatoid arthritis from the northern half of Australia where tropical or sub-tropical climates obtain but he has seen many cases from the southern half especially the eastern fringe of the continent where the altitude, prevailing winds and rain fall create a much cooler climate. Again the comparative pathology of rheumatism has not yet had the study it deserves though it is known that diseases which closely resemble acute and chronic rheumatism in man occur in domestic animals. Nor have clinical and experimental observations on man yet been exhausted. The experiments of Lewis and Kellgren carried out with the simplest of technique are bringing precision to our ideas of fibrositis and muscular rheumatism and of the reference of pain from the tendons and muscles while Halliday has shown how often pain in the locomotor system is perpetuated by purely psychogenic factors.

So vast are the problems raised by rheumatism and so numerous are the sufferers that it has been questioned whether the voluntary hospitals can cope with them and there is undoubtedly need for the provision of local clinics and special institutions for treatment. Whatever developments occur along these lines it seems certain that the great spas will remain centres of specialized knowledge and equipment for the investigation and treatment of rheumatism. For 200 years the Royal Mineral Water Hospital at Bath has opened its doors to poor people who have suffered from rheumatism and latterly more than 95 per cent have come from a distance. It has now become necessary for the hospital to seek a new site and more ample accommodation for its work in treatment and research. Doubts may sometimes be felt about the wisdom of specialization or of *ad hoc* research but unless special centres exist for the study of rheumatism the danger is rather that the profession may tolerate it as one of the inevitable ills of humanity. This *Survey* is therefore a reminder and a stimulus—a reminder of the extent of the problem and our present knowledge and a stimulus to further work.

### MEDICAL PRACTICE IN THE RAW

*Behind the Night Bell* By F. G. Layton (Pp 289 8s 6d net) London: Faber and Faber 1938.

Now that various and not always creditable aspects of medical practice are constantly before the public eye it is a relief to read a book which deals with the life

of the slum doctor in a sane accurate and objective manner. Dr Frank Layton has worked as a general practitioner for more than forty years, mostly on the edge of the Black Country. As he says in his introduction it has not been easy. Doctoring poor people seemed at the start almost as hopeless as building a house without tools or building materials. He always found building materials however in men, women and children for he soon appreciated the real truth of doctoring the poor while his immediate job was to deal with their bodily ills, his ultimate job was to try to understand the people themselves. One of his chief objects in writing this volume of reminiscences and reflections was he says to point out how real a thing psychology—merely another word for understanding—has become in the life of a hard-worked general practitioner. The result he may seem somewhat inconsequent. That is no fault for so is life and the book would not be like it if it were tidy. He is not a crusader and has no moral Charles heads. He has some outspoken things to say about one or two aspects of the official mind but in its tendency to certify as mental disease things people who are really suffering from adolescent muddle. His chapter on neurosis and its purposefulness is very wise and quite in accordance with the results usually expressed in less simple language of psychological research. He is much to be trusted on the mental aspect of illness and trouble for he has learned his psychology where Jung tells the doctor to learn it—in contact with human beings in every situation. It is to be hoped that many people, both doctors and laymen, will read this book for it contains the intangible but true and eternal meaning of medical practice.

### TREATMENT OF TUBERCULOSIS

*Therapie der Tuberkulose* Edited by D. J. Berberich and Dr. P. Spiro. 2 Volumes (Pp 845 2s 6d unbound 2850 Fl bound) Leiden: A. W. Sythoff's Uitgevers Maatschappij N.V. 1937.

It is increasingly being realized that tuberculous disease even when apparently localized in one organ must be regarded as a systemic infection. Such a view assists in the diagnosis, prognosis and treatment of the disease. The frequent artificial distinction in textbooks between pulmonary and surgical tuberculosis is therefore to be deplored. Professor Berberich and Dr. Paul Spiro with the collaboration of workers in various countries have attempted to produce a treatise on the therapy of tuberculosis in which the unity of tuberculous disease is kept in the forefront. The title underestimates the scope of the book which summarizes the modern view on most aspects of clinical tuberculosis.

The first volume contains discussions of the problems that lie at the basis of the treatment of tuberculous disease anywhere in the body. Professor Fraenkel of Heidelberg writes an excellent historical sketch for many years he has witnessed and himself assisted in the work that have led from the first paper on tuberculin read by Koch to the most modern developments in the surgical treatment of phthisis. A fairly complete account of the bacteriology of the tubercle bacillus is given by Bauer of Istanbul. Walter Pagel of Papworth writes as he is becoming more and more known in this country writes three authoritative chapters on immunity, on pathological basis of healing processes and the anatomical and experimental findings after therapeutic procedures. An excellent chapter by Fraenkel discusses the role of radiotherapy in prognosis and treatment of tuberculosis. The sections on tuberculin in diagnosis and treatment of the

other hand, have less to commend them Wallgren follows with a brief discussion on protective vaccination, the use of dead bacilli being too summarily dismissed Epidemiological considerations receive scanty treatment by Hollo of Budapest The remainder of the volume consists of a good unbiased account of the chemotherapy of tuberculosis by Brieger, now attached to the Research Department of Papworth, and of an interesting discussion, by the same author, on occupational therapy and social rehabilitation, including a description of the modern physiological methods used to determine working capacity

The second volume comprises individual accounts by various authors of the treatment of tuberculosis in the different organs and systems The quality of the chapters varies greatly, as is inevitable in a many-author production The accounts of the treatment of tuberculosis of the upper respiratory tract by Berberich, of the surgical treatment of phthisis by Hollo, and of the treatment of tuberculous eye conditions are particularly good Short discussions are included on tuberculosis in old age, tuberculosis and marriage, tuberculosis and pregnancy, tuberculosis and diabetes, and on the psychological aspects of tuberculosis

This work is a useful addition to tuberculosis literature It is very readable But the almost total absence of illustrations reduces the value of the book except to those who are already familiar with the practical application of the subjects discussed in it

### FUNCTIONAL INVESTIGATIONS

*Les Explorations Fonctionnelles* By Noel Fiessinger (Pp 432, 65 figures 70 fr) Paris Masson et Cie 1937

Probably at least half the patients in the medical wards of any general hospital to-day have been admitted "for investigation," and in this book Dr Fiessinger has endeavoured to collect and discuss the methods available for this purpose It is unfortunate that clinical and laboratory investigations are so often regarded as anti-thetic when they should be complementary, for the special examinations permit one to see further and better than simple observation of the patient Dr Fiessinger recalls two clinical histories of Boerhaave—Jean, Baron de Warsenaer, who succumbed to a pneumothorax following perforation of an oesophageal ulcer, and the Marquis of Saint Auban, who died of a mediastinal tumour How could such cases be diagnosed before the introduction of special methods of investigation? The author discusses in simple language the methods and indications for examination of the various organs, giving the theoretical basis and interpretation of the various tests but not going into details of procedure

The book is addressed to the clinician, and not to the pathologist or technician Nearly half of it is devoted to the liver and the kidneys, and this seems out of all proportion to the reliability and clinical value of tests of these organs The blood-forming organs are well done, with good accounts of spleen and marrow puncture On the other hand, the section on the endocrines is poor, surprisingly so when one learns that Dr Fiessinger is the author of two books on endocrinology In the discussion of Addison's disease no reference is made to the value of radiology and of low salt diets in diagnosis There is a good account of the sex cycle and sterility in the female, but nothing about the male We also looked in vain for radiography of the heart, kymography, tomography, cephalography, and ventriculography The book is therefore lopsided and incomplete It is based on a series of lectures, and it gives the impression that the author

had begun with high enthusiasm, had then got lost in the thickets of hepatic and renal function, and finally had to finish his course in haste It cannot be recommended for general use, but will be of great interest to more advanced students in giving an indication of French methods There are no references to the literature, no bibliography, and no subject index

### THE POINTING TEST OF BARANY

*Der Zeigerversuch* Prüfung einiger Voraussetzungen für seine klinische Brauchbarkeit By Wilhelm Behrman Uppsala Almqvist and Wiksells Boktryckeri A B

This monograph presents the results of a detailed investigation into the pointing test of Barany A survey of the literature shows that different workers use different methods and have not been able to agree as to which is the best In this clinical investigation eleven different techniques have been tested, and of these the most reliable is shown to be that in which the extended arms held above the head are simultaneously brought forward to the horizontal against a mark with the eyes closed Any error is allowed to remain uncorrected on repeated pointing Using this technique on a large number of normal subjects, the variability both for spontaneous pointing and for pointing after stimulation has been worked out Detailed tables of the fields of variation for the different techniques are given, and should be of great help in determining whether a patient has pointed spontaneously within or without the limits of the field of variation For pointing after stimulation the field of variation increases considerably, and may sometimes be double that of spontaneous pointing

This is a valuable addition to the literature of the labyrinth, and may be read with advantage by all those interested in neuro-otology

### A TREASURY OF ROUTINE PROCEDURES

*Practical Procedures* Edited by Sir Humphry Rolleston, Bt G CVO KCB, MD, FRCP, and Alan A Moncrieff, MD, FRCP (Pp 293, 66 figures 10s 6d net) London Eyre and Spottiswoode, Limited 1938

We are most of us by now familiar with those attractive instruction books which the makers kindly send to us when we buy a new car We study them with just that degree of intelligence and interest which Nature has vouchsafed to us in the matter of motor cars Now has come a somewhat similar kind of book called *Practical Procedures*, edited by Sir Humphry Rolleston and Dr Alan Moncrieff, with a preface by Sir David Wilkie In the course of seventeen chapters we are told by a team of acknowledged experts just how to carry out any of the common routine practices which each of us in his daily round may find it necessary to perform As Sir David Wilkie points out, one of the advantages of holding hours appointments after qualification is that these methods are learnt then as a matter of course By no means all are so fortunate as to serve as hospital residents, to the and to the older men to whom some of the procedures described may appear slightly novel, this book should make a particular appeal A synopsis of the contents will indicate the scope of the book plaster of Paris technique, administration of fluids, indications and technique for blood transfusion, the value and interpretation of blood counts, diagnosis and treatment of poisoning, estimation of blood pressure, technique of aspirating pleural effusions, the use of two-way and three-way systems, catheters and the avoidance of sepsis, clinical examination of the urine, circumcision in children, injection technique

minor surgery of the skin local anaesthesia, soft tissue injuries lumbar punctures syringing the ear

There is a hostelry in the City of London with a world wide reputation for the unique excellence of its steak pudding with etceteras. The feeling of satisfaction and repletion with which the gourmet rises after sampling that pudding may be experienced in a more spiritual sense by the keen practitioner who takes the trouble to read this book. It need only take him a short time but in hour or two will seldom have been spent more profitably for *Practical Procedures* is a veritable Golden Treasury of most valuable information

## Notes on Books

*Normal and Diseased Regulation in the Human Organism* (Jena Gustav Fischer RM 12 paper RM 13.50 board) consists of twenty five lectures delivered before the International Postgraduate Course of the Berlin Academy for Postgraduate Instruction from October 26 to 31 1937

Among the numerous interesting problems discussed attention may be drawn to the following papers. The action of the internal secretions by H W Bansi of Charlottenburg diseases of the pancreas and hormonal metabolic disturbances by Professor Friedrich Lamber of Berlin regulation of the acid base equilibrium by K Gollwitzer Meier of Hamburg regulation of sleep by H Schriever of Berlin regulation of organic metabolism by Herman Bernhardt of Berlin regulation of growth and development by Professor Curtius of Berlin allergy and inflammation by Professor F Klinge of Munster regulation of the circulation by S Dietrich of Berlin reciprocal action between skin and internal organs by Professor H Gottron of Breslau the connexion between metabolism circulation and respiration by Professor Hermann Rein of Gottingen the relations between hormones vitamins and ferments by Professor Werner Kollath of Rostock and the endocrine system and the organ of hearing by Hermann Barth of Berlin

The little work entitled *Fever for Nurses* (Edinburgh E and S Livingstone 5s) by Dr GERALD E BREEN senior assistant medical officer at the North Eastern Fever Hospital (LCC) is based on lectures given by him to nurses in recent years. In addition to a concise and lucid account of the diseases usually admitted to fever hospitals chapters deal with venereal disease the eye ear nose and mouth operative procedures and manipulations the dosage of drugs in common use and a selection of questions set in State examinations for fever nurses during the last three years

Dr W F CHRISTIE whose recent exceptionally clear and concise book on obesity was reviewed in these columns has now produced a monograph *Ideal Weight* which is virtually a summary of physiology in its relation to body weight in such a way as to be easily understood by the lay person. Calories and similar terms are made clear to the non technical mind and the work contains a very useful analysis of some of the common foodstuffs and the food value of various dishes and drinks. Diets suggested for the maintenance of the optimum weight in patients who have already reduced by drastic means are explained in full and will be found to be of the greatest help. In short the book is a useful adjunct to his previous work on obesity. It is published by Heinemann at 5s

A series of papers by Dr J GRANDSON BYRNE on *The Physiology of the Middle Ear* is published in book form by H K Lewis and Co at 18s. The study has been designed to demonstrate whether the ossicles with the tensor tympani and stapedius muscles act together as an apparatus of accommodation analogous to the ciliary

muscle of the eye. In studying the problem the question of reciprocal innervation has to be investigated. The method adopted is to examine the hypersensitiveness of the motor mechanism to adrenaline after section of the post ganglionic paths supplying the muscles. For example after interruption of the efferent path supplying the tensor tympani the retracting mechanisms in the tensor tympani are tested with adrenaline. The middle ear is left intact and kymographic tracings are taken directly from the membrana tympani of the living animal. The author considers that his experiments of which full protocols are given show an analogy between the mechanisms of the tensor tympani and the ocular muscles concerned in accommodation. The work is an elaborate study of the mechanism producing proptosis and retraction of the membrana tympani examined in great detail

## Preparations and Appliances

### PROCTOSCOPE FOR INJECTION OF HAEMORRHOIDS

Dr PHILIP H DALGLEISH (Hull) writes

Having been dissatisfied for some time with all the various types of proctoscope on the market I have devised a model for use in the injection of haemorrhoids. The advantages of this new model are that the whole operative field is visible

at the same time the haemorrhoids do not project into the lumen of the instrument, and there is no irritation to cause discomfort to the patient and be a nuisance to the operator.

The instrument has been made for me by Messrs F D. Johnson and Co., who are supplying it with illumination from a battery in the handle or from a separate battery.

### AN ERGOT PREPARATION

"Neo-femergin" (Sandoz Products 134 Wigmore Street W1) is a mixture of two parts of ergotamine tartrate and one part of ergometrine (ergobasine) tartrate. The investigation of the ergot alkaloids has been a long and difficult process but it would appear that the one most recently isolated—namely ergometrine—is the most important member of the group on account of its rapid action. Ergotamine on the other hand is characterised by a prolonged action which is exerted slowly. The combination of the two alkaloids in "neo-femergin" is intended to have an effect which is both rapidly produced and long continued. Messrs Sandoz have prepared an interesting pamphlet which gives an account of the history of the ergot alkaloid and of practical colloidal and clinical studies made with "neo-femergin". They consider that the compound is particularly well suited for post partum use.

## INSULIN FOR SCHIZOPHRENIA

Encouraged by the favourable influence of insulin on withdrawal symptoms occurring in the treatment of morphine addiction, Manfred Sakel<sup>1</sup> started the insulin treatment of schizophrenics in the Vienna Psychiatric Clinic, and made the first communication on his results in 1933. Since then the interest aroused has been great, and the treatment, which rests entirely on an empirical basis, has now been tried in Switzerland, Poland, Hungary, Yugoslavia, Germany, Russia, France, and Norway, as well as in this country and the United States. The subject had advanced so far by May of last year that an international congress was held in Munsingen, Switzerland, at which workers from different countries compared their results, it was computed that by then some two thousand schizophrenics had been treated by Sakel's method. The atmosphere of enthusiasm at the congress pervades nearly all the addresses published in the report,<sup>2</sup> and subsequent publications seem to show no slackening of interest. But it has not yet been possible to reduce the difficulties and dangers of insulin treatment below a certain level. The attempts of some workers, particularly in America, to obtain results with hypoglycaemia insufficient to produce coma, with treatment at longer intervals than once every two days and with a reduced number of treatments, have been attended with but indifferent success.

Enough insulin must be given in the fasting state to produce coma, which should last one to one and a half hours before being interrupted, from sixty to ninety such comas may be required before all possible benefit has been obtained. Sakel has laid it down that the corneal reflexes must be absent, or at least that there should be an extensor plantar response, before the coma can be considered deep enough. In such a state the patient is for all practical purposes in a state of profound anaesthesia and has to be watched continuously by eyes skilled to detect any change in his condition. Such complications as epileptic fits and failure to come round after glucose has been given by intranasal tube, as well as the fortunately rare cardiovascular collapse, require the immediate intravenous administration of glucose. If the risks are great the rewards may be considered to outweigh

these in view of the intractable nature of the disorder. Those who have employed this method of treatment have observed that a change in the patient's mental state coincides with the daily hypoglycaemia and that this change tends to last for a period that increases progressively after the termination of each coma, finally, in the favourable cases the change for the better persists. Dr. Muller reported to the Swiss congress that of the 495 cases which had then been treated in Switzerland 40 per cent had made a full social recovery. The recovery rate was 57 per cent in those patients who had been ill for less than one year. Alleviation of the symptoms is claimed even in patients obviously beyond hope of recovery, withdrawn and difficult patients have become more social and able to behave in a more normal manner. It is suggested that treatment with insulin produces a better type of remission—and this has been estimated to occur naturally in from 5 to 25 per cent of cases—but whether it also prolongs the length of the remission is at present not known. Much further research will be required before this point, and many others, can be established.

The voices of warning and scepticism have not been wanting amidst the general enthusiasm. Professor Adolph Meyer has drawn attention to the difficulties of making an accurate prognosis and to the impossibility of saying how a treated case would have progressed without treatment. It is clear that if the schizophrenics have been specially selected for treatment their hypothetical recovery rate in the absence of special treatment cannot be fairly deduced from that of an average group. It has even been suggested that not all the patients treated have been genuine cases of schizophrenia, and that their recovery rate has been enhanced by the inclusion of cases with a pronounced affective element. It is, however, difficult to suppose that such a large group of psychiatrists as were represented at Munsingen had so radically altered their standards of diagnosis, when it came to the selection of cases for insulin treatment, as to include many cases of affective disorder, and most psychiatrists would hesitate to back their judgment to the extent of selecting a group of schizophrenics of whom as many as 57 per cent would make a full social recovery. Less benefit is obtained in patients who have been ill for a long time. In cases of over two years' duration Muller found only 11 per cent of recoveries, and in twenty-seven cases of over five years' duration Plattner and Frolicher<sup>3</sup> did not observe one. If, then, the treatment is to be of value it should be started as soon as the diagnosis of schizophrenia can be made with confidence. The early diagnosis of schizophrenia

<sup>1</sup> *Neue Behandlungsmethode der Schizophrenie*. Perles, Vienna, 1935.

<sup>2</sup> *Schweiz. Arch. Neurol. Psychiat.* (1937) Ergänzungsheft zum Band 39.

<sup>3</sup> *Z. ges. Neurol. Psychiat.* 1938, 160, 735.

will become of increasing importance. The attention of medical practitioners will have to be directed to this point and it will be desirable for students to have special training in the early recognition of the disease. If facilities for treatment are adequate it would not seem justifiable in an otherwise suitable case to postpone treatment with the possibility of a spontaneous remission in mind. Some authors have found a marked worsening of the prognosis with treatment when the illness passes into its second six months. As a corollary it follows that where the facilities for treatment are less than adequate for the potential demand the most recent cases should in general be preferred.

What the ultimate importance of insulin treatment may be we cannot yet forecast. Much depends on whether it shows any decided advantages over convulsion treatment with cardiazol. The latter, though frightening and disagreeable for the patient is certainly simpler and safer and it appears to give comparably favourable results. It is likely to become the method of preference in mental hospitals in which adequacy of medical staffing might easily become a difficult administrative problem with the introduction of insulin treatment. The percentage of failures with both methods even with recent cases is considerable but it may perhaps be hoped that the failures of one method will provide some of the successes of the other. The two methods are not mutually exclusive and many workers have reported encouraging results from a combination of both. Insulin treatment is drastic and costly in the time and attention it demands of both medical and nursing staffs. It is a method only for employment in a hospital or properly equipped institution and by a fully trained personnel. With increasing experience and skill many of the dangers become less real but some there will always be. Nevertheless it has stimulated therapeutic activity by what has already been attained and it will encourage research by the problems it has raised and leaves still unanswered.

### SHIPS AND SEAMEN

We are accustomed to think of our Merchant Navy as the finest in the world and to boast of our ships and our seamen. There is much justification for pride for our ships are well found and our men still live up to the highest traditions of the sea. The passenger in a British ship has no cause for anxiety as to his safety or comfort and the merchant ships his goods with confidence in British bottoms. In every respect save one our ships are unequalled. Give one! Where then have we failed to maintain our pre-eminence? In two

articles entitled 'Ships and Men' the Labour Correspondent of the *Times* has answered this question with full knowledge of his subject a full sense of responsibility in his criticisms and a desire to be fair to both owners and men.

It is in the standards of living accommodation for the crews of our ships that we have fallen behind. For many years port medical officers have drawn attention to this but neither port medical officers nor even the Ministry of Health have anything whatever to do with ships under construction. They are not consulted in matters of hygiene or sanitation and not until a ship is completed and actually in commission have they any opportunity of inspecting the housing of passengers or crew. While the ship is building everything is controlled by the surveyors of the Board of Trade who in relation to the hygiene of ships must carry out the Board's Instructions as to the Survey of Masters and Crew Spaces. The Board has recently revised these instructions and in new ships crew quarters will be vastly improved though as the *Times* Labour Correspondent points out British ships which do no more than comply with the new requirements will yet be inferior in this respect to the ships of the Northern European countries and the United States. Moreover well qualified as the Board of Trade surveyors are to deal with everything concerning the seaworthiness of ships and the safety of life at sea they have no special training in hygiene and consequently in the future as in the past they will so far as crew accommodation is concerned often fail to make the best practical use of the instructions which are issued for their guidance. If a Port Health Authority criticizes the crew quarters in a new ship the owner at once replies that they have only recently been passed by the Board of Trade. He feels aggrieved as do also the Board of Trade surveyors who no doubt have carried out their instructions literally but perhaps without a real appreciation of their significance and therefore without careful thought as to how the space allocated to the crew in a particular ship may be fitted out so as to provide the healthiest and most comfortable conditions for the men who will have to make it their home for weeks or months. There still remain a few surveyors as also some masters whose standards are those of their own early days at sea who take the view that what was good enough for them is at least good enough for the present-day seamen the number of such reactionaries is fortunately dwindling.

Neither the Board of Trade however nor its surveyors are primarily responsible for the deficiencies in crew quarters. The former can only issue general instructions and the latter though

they can exert considerable influence, cannot enforce more than bare compliance with such instructions. The shipowner and the shipbuilder must really share the blame. In many cases it is quite obvious that nobody has given any serious thought to the comfort and convenience of the crew. The shipbuilder's excuse will be that competition is keen, and that if he introduces into his plans for crew accommodation anything more than the bare requirements of the Board of Trade his tender will be higher than that of his competitors who are quoting on minimum standards. The shipowner will say that international competition is so great that he cannot afford to provide luxuries. But the retort might often be that neither of them takes the trouble to consider what improvements can be effected without additional expenditure. They have a stock type of accommodation, and it is provided again and again. Fortunately there are a number of British shipowners who have always taken a keen interest in the welfare of their crews, and there are British ships with crew accommodation which is unsurpassed by that in the ships of any other country.

The *Times* Labour Correspondent acknowledges that the new Board of Trade requirements mark a great advance in the housing of seamen, but observes that "they will do no more than establish minimum standards of health and comfort." It is, however, the existing ships, built before the new instructions were issued, with which he is most concerned. The life of such ships may be anything from twenty to thirty years, and "in the meantime thousands of sailors and firemen will be going to sea in conditions that are not creditable to a seafaring nation unless shipowners resolve that the accommodation which is below standard shall be improved to the utmost extent." It would be unreasonable to expect an owner to carry out extensive alterations in a ship which he expects to scrap in a year or two, but ships which are not more than, say, fifteen years old ought to be brought as nearly as possible up to the new standards. Recommendations are put forward by Port Health Authorities—these cannot be enforced, but shipowners should nevertheless give them serious consideration and make a sincere effort to put them into effect or even improve upon them. The Board of Trade and Port Health Authorities must work in harmony, there must be no departmental jealousy, no feeling that every suggestion from one is a criticism of the other. The Board of Trade has the greater influence, but the Port Health Authorities have the greater knowledge in matters of hygiene. If they pull together much can be achieved in existing ships, if they disagree not they but the mercantile marine will suffer in reputation and efficiency.

At the same time the masters and crews of ships must play their part. It is unfortunately true that speaking generally, standards of cleanliness and personal hygiene are higher among the Scandinavian seamen than among the British. Even Port Health Authorities have tended to advocate the severest simplicity in crew accommodation because it has been found that any elaboration has meant more dirt and greater risk of infestation with vermin. To take one example—wooden sheathing of quarters certainly adds to warmth, dryness, and a general appearance of comfort, but because sheathing harbours bed-bugs it has been discontinued and the bare iron surfaces are simply coated with cork cement to minimize "sweating." This is a most unsatisfactory procedure, a rough surface which harbours dirt is created, and the more it is painted the less efficient it becomes in the prevention of dampness from condensation. Probably close-fitted panels of strong plywood could be made vermin-proof and would make quarters much more comfortable and attractive. Again, wash basins and spray baths are often neglected, and sometimes brass and copper fittings are stolen, so that the seaman is usually provided only with a bucket for washing. Fresh water, particularly hot fresh water, is wasted if it is too readily accessible, and fresh water means space and weight, which mean money in a ship. Many an owner, and indeed many a port health officer, has been discouraged by the way crews have misused good accommodation, and has wondered whether it is worth while to try to make them more comfortable. The best men go to the best ships and stick to them, and no doubt improved conditions would attract to the sea many more men of the right type. The worst ships get the worst crews, and so a vicious circle is set up. But ashore it is no longer held that the slum dweller will make a slum wherever he is housed. He has to be encouraged and subjected to a certain amount of surveillance, but in the majority of cases he responds to his new environment, and his standards of self respect, and consequently of behaviour, are raised. So it will be at sea, particularly if the master and his officers will take an interest in the crew's welfare. A harsh discipline, such as was the rule in sailing ship days, would not be tolerated, but instances could be given of sister ships, in one of which the crew's quarters are dirty and untidy and the crew discontented, while in the other the quarters are clean and well kept and the crew cheerful, the difference being entirely due to the personality of the master or the chief officer.

In coasting vessels conditions are often far worse than in foreign-going ships, for quarters are cramped and hours of work excessive. If

men ration themselves and buy in the cheapest market there is no proper provision for the storage of food no cook is shipped the crew are often too tired to do even such cooking as they are capable of doing and the eternal cup of strong stewed tea completes the ruin of their digestive powers. It is little wonder that when employment ashore is good it is difficult to man the coasting vessel and the tramp steamer.

Tradition dies hard in the Merchant Service. True we have moved on from the salt beef the salt pork the weevily biscuits and the brutal discipline of the days of sail but only lately have we begun to apply in ships the improvements in living and working conditions which for years have been steadily taking place ashore. Obviously owners cannot be expected to run their ships at a loss the industry has passed through a long period of depression operating costs have risen manning scales have been increased competition has become keener. But it is contended that if those responsible for the design the building and the running of ships had carefully considered how much they could afford to do for the crew and not merely what was necessary to meet the requirements of the Board of Trade great improvements would have been effected and many more of the best type of officer and man would have been and would continue to be attracted to a seafaring life.

### IS THOROTRAST SAFE?

The suspension of thorium dioxide known as thorotrast has now been used for some years by intravascular injection to produce radio opacity. The particles are phagocytosed in the reticulo endothelial system and a sufficient dose consequently renders the liver and spleen opaque. Hepato-lyenography was the first use to which thorotrast was put. More recently it has been employed mainly for arteriography which requires a smaller dose and sometimes for outlining the ventricles of the brain. Thorium dioxide has two rather forbidding properties it is retained indefinitely in the tissues in which it comes to rest and it is radio active. The fact that radio active substances may consequently be carcinogenic is now generally familiar. The best known example of this effect was seen in the girls employed in painting luminous dials in an American watch factory by pointing brushes with their lips they contaminated their mouths with small amounts of the paint which contained radium and mesothorium and although the factory concerned was closed in 1924 new cases of osteogenic sarcoma among its employees were still being diagnosed in 1931. We drew attention three years ago to the work of Roussy, Oberling and Guerin<sup>1</sup> who first showed that thorotrast is in fact carcinogenic at least in the rat and more recently F. R. Selbie<sup>2</sup> has reported the production

of malignant tumours in mice by injecting it subcutaneously. The former even recommended thorotrast as a convenient and reliable agent for producing experimental tumours and Selbie strongly condemns its use in patients. W. M. Yates and E. R. Whitmore<sup>3</sup> take a different attitude based on the subsequent study of patients to whom thorotrast was given for the purpose of hepato-lyenography. These fall into two classes consisting of sixty four who died from a few days to three years after the injection in whom the study could therefore be a histological one of the tissues concerned and ten who are still alive at intervals of from four to six years after the injection. In the latter the liver and spleen were still radio opaque at the end of the time the only change exhibited being some degree of migration to neighbouring lymph nodes. It appears therefore as indeed is to be expected that anyone who is given thorotrast keeps it for life. These patients had experienced no ill effects they are actually no better in some cases than others with the same diseases such as leukaemia and hepatic cirrhosis so treated. The histological study of cases coming to necropsy showed no evidence of any injury to the liver or spleen or of any abnormal cellular reaction there and a subcutaneous fibrous nodule due to escape of the fluid during injection showed no proliferative activity when excised four and a half years later. It is recorded that the bone marrow was ever examined. These findings are encouraging so far as the future they will not altogether allay the anxiety felt by the over patients who have been submitted to this procedure. Thorium dioxide is evidently not as actively carcinogenic as radium which in the case recorded by Ross<sup>4</sup> gave rise to a malignant tumour in less than three years but there is still no guarantee that the effect already demonstrated in mice will not be paralleled in man. The process in mice is slow and an equivalent period in human life is unfortunately not less than ten years. Those interested in the subject will find much food for thought in the recent review of the thorotrast literature based on 13 original papers by Reeves and Stuck. In the view of these authors there are serious contraindications to almost every form of its use and they are impressed by the fact that most of those who were originally enthusiastic about thorotrast have ended by condemning it.

### DASHBOARD DISLOCATION OF THE HIP

Not long ago we draw attention to the bumper tractor which may be sustained by an unvarying pedestrian. Further investigation of the pathology of motoring has now brought to light the "dashboard dislocation of the hip." Thirteen of a series of twenty cases of dislocation of the hip described by F. W. Kinser and Frankel were caused by the impact of the tibia or of the knee against the dashboard of a motor car involved in a collision. The patients who sustain

Am. J. Surg. 57 19 195 193  
J. Pa. 1 57 19 35 193  
Med. 1 19 3 17  
Br. J. Med. 1 19 3 1 193  
J. Bone J. Surg. 19 20 193

a "dashboard dislocation" is usually a passenger sitting in a front seat beside the driver, the hip is in the flexed and adducted position, and the force of the impact against the instrument panel is transmitted through the femur to the hip-joint. This may result in a simple dislocation or a dislocation with fracture of the posterior rim of the acetabulum. Occasionally a fracture of the tibia or of the patella may be brought about in the same way. A particular lesion is less likely to be overlooked if the ways in which it is commonly caused are known, and recognition of the possibility of bumper fractures and of dashboard dislocations is therefore important. Not long ago a standard textbook on surgery stated that traumatic dislocation of the hip is rare, and, as a type of injury apt to give rise to it, instanced the forcible abduction due to a patient having one leg in a moving boat and the other on a jetty. There can be no doubt that the condition is not so rare as was thought and that the motor car is responsible for many of the cases of traumatic dislocation of the hip met with to-day.

### HUMAN TUBERCULOSIS OF BOVINE ORIGIN

Last year we drew attention to reports on human tuberculosis of bovine origin submitted to the *Office International d'Hygiène Publique*.<sup>1</sup> Several further notes have now been published.<sup>2</sup> In the U.S.A. the disease is apparently being eradicated as the result of slaughter of all infected cattle and by pasteurization of milk. In 1917 tuberculin tests were carried out on 20,101 animals, and 3.2 per cent reacted positively. In 1936 there were only 0.7 per cent of positive reactors among 22,918,038 animals. About 40 per cent of the population still consume crude milk. This applies particularly to rural districts and small towns, but in towns with a population of 500,000, of all the milk sold 98 per cent is properly pasteurized. Human pulmonary tuberculosis due to the bovine bacillus is very rare in Italy. Only seven such cases were found among 552 consumptives in 1932 and 1933. Cattle suffering from tuberculous disease must be notified and isolated according to the Italian regulations, and the sheds in which they were kept must be disinfected. Only tuberculin-negative animals may be introduced into herds giving milk intended to be consumed in the crude state, and they must be re-tested every six months. Germany's regulations for the prevention of tuberculosis in young calves are stringent. Australia has no legislation specifically directed to this end, but the incidence of tuberculosis in cattle is low, only about 8 per cent are infected and "open" cases are rarely seen. The tuberculin test is, however, being increasingly used. In New Zealand, too, this problem is not so serious as in many other countries, about 20 per cent of extrapulmonary infections in man are caused by the bovine type of bacillus. The report from Poland includes a plea for the setting up of a special commission to decide on the best method of examining market milk for tubercle bacilli, and to arrange for a complete

comparative study of the methods of pasteurization practised in various countries. A valuable paper recently published on human tuberculosis of bovine origin is by A. S. Griffith,<sup>3</sup> who states that "the latest findings in regard to this intractable problem should be made widely known, since they prove beyond doubt that bovine tuberculosis is a serious menace which must be fought with the utmost vigour." The Royal Commission on Tuberculosis, in its interim report in 1907 and in its final report four years later, urged the necessity for measures being taken to prevent the sale or consumption of infected milk. Yet this country still has a milk supply so infected that often 5 to 12 per cent or more of samples of ordinary churn milk contain tubercle bacilli, and more than 40 per cent of the milking cows in this country are tuberculous. Griffith describes his investigation of the incidence of the bovine bacillus in pulmonary tuberculosis and mentions the results of other workers. In 1922 only four cases of "bovine" pulmonary tuberculosis had been recorded in this country, and none had been noted abroad. At present the total number discovered in Great Britain is 163. In Denmark K. A. Jensen found bovine bacilli in the sputum or gastric contents of 5 per cent of 1,774 cases of pulmonary tuberculosis, in Holland A. C. Ruys found them in 6.4 per cent of 204 patients. B. Lange in Germany cultivated bovine bacilli from twelve patients, all "cattle contacts," in three of whom the human bacillus was also isolated.

### INTELLIGENCE AND FAMILY SIZE

The problem of differential fertility is one which is of the greatest practical significance, and it is not unnatural that the relationship between size of family and social status should have been investigated extensively. It is apparent, even upon casual observation, that the members of the wealthier classes have fewer children than members of the poorer classes. The interdependence of family size and intelligence is less easy to ascertain because methods of measuring mental ability have to be devised and standardized before such a study can be undertaken. A recent publication, by Roberts, Norman, and Griffiths,<sup>4</sup> is the third of a series in which work carried out at Stoke Park, under the auspices of the Burden Mental Research Trust, is reported. The quality of this investigation is in all respects of a very high order. The investigators first took very careful steps to standardize the Otis series group test of intelligence in such a way that the series of children of different ages could be accurately compared. They proceeded to investigate the distribution of intelligence in the entire community of a selected area by testing every child between specified ages. If accurate material collected in their survey has now been analysed from the point of view of family size, and there are, no doubt, other types of analysis to which the material will lend itself. A comparison of the sibship of each child with the Otis test score in 3,305 cases leaves no room for doubt that the

<sup>1</sup> *British Medical Journal* 1937, 1, 980.

<sup>2</sup> *Bull. Off. int. Hyg. publ.* 1937, 29, 1649.

<sup>3</sup> *Tubercle* 1937, 18, 529.

<sup>4</sup> *Ann. Eugen.*, Camb., 1938, 8, 178.

exists in the community a significant inverse relation ship between family size and intelligence the correlation is  $-0.224$ . A parallel study of 1271 children who belonged to specially selected groups and who were given the Stanford-Binet tests led to similar results and the corresponding negative association was even stronger when the Binet test was used. The authors give reasons for supposing that the Binet test is a better measure of general intelligence than the Otis test. The partial correlation between intelligence and family size for constant social conditions has been shown to be highly significant by previous studies in the United States. In the Stoke Park investigation however differential fertility with respect to intelligence was found to be diminished if the children were first classified according to social status. For this purpose data from four types of schools which catered for children of different social classes were separately analysed. Within the limits of the highest social class a negative association between family size and mental ability was not detected. The average number of sibs of children in private schools was so small that the reproductive rate it represents must be far too low to ensure survival. The number of sibs was far smaller even than would be expected if it were merely due to the superior average intelligence of these children. This fact clearly indicates an association which is independent of mental grade between social class and fertility. The survey has been so well conceived that these results cannot be criticized as the results of some previous surveys have been on the grounds that the sample of children tested is not representative or that the tests employed are inaccurate. Future investigators who propose to work on similar problems will be well advised to study in detail the methods of Dr Fraser Roberts and his colleagues.

### PAINLESS SELF-MUTILATION

Some almost incredible examples of insensitiveness to pain were mentioned to the Hunterian Society when Dr J H Hunt addressed it on his experiences among Indian fakirs. His remarks related to a sect of Moham medan fakirs at Hyderabad whose annual festival at which self-mutilation occurred had never before been seen by Europeans. Dr Hunt was able not only to show flashlight photographs of the dervish-like dances (which took place in their burial ground at night) but also to exhibit metal spikes and skewers which they used in their frenzies. The sect was founded in Persia in the tenth century the founder believing that the way to heaven was by self-torture and his descendants followed his example. His fourteenth direct descendant migrated to Hyderabad three hundred years ago and there the annual festival was continued in his family with occasional performances in the palaces round about. Lord Curzon in his *Tales of Travel* described similar performances which took place in a dimly lit mosque in North Africa the people in a cataleptic state engaging in an orgy of self-mutilation. Dr Hunt said that apparently no pain was felt and although punctures and gashes were inflicted they seldom bled. A sharp skewer would be run through the cheek

or still more remarkable through the neck coming out on the other side or through the abdominal wall but in such a way as not to touch the peritoneum. The ability to pass a skewer through the neck was the most interesting exploit. If the man were watched it would be noted that he manipulated the other side of his neck with his hand what he did was to pull the vital structures forward so that the skewer passed behind the trachea and bronchus and in front of the vertebral column. A manipulation that was outwardly the most horrifying was the easiest to explain. This was the placing of a sharp instrument behind the eye so that the eyeball was levered out apparently no hurt was sustained and visual acuity remained normal in the eye so maltreated. When these people were children they would put a small stick to the corner of the eye with the result that the eyeball came out a fraction of an inch and with repetition a complete exophthalmos could be produced. The instrument did not actually touch the conjunctiva it went into the corner of the outer canthus. Dr Hunt said that various operations could be offered for the insensitiveness to pain. Many of these people through long usage had a good deal of scar tissue which was relatively insensitive and did not bleed easily and this accounted for the walking and lying on beds of nails. Drugs especially Indian hemp might account for much but the people swore they did not use drugs. The most likely factor was self-hypnotism assisted by reverberations of drums which never ceased throughout the performance. The absence of bleeding might be explained by the fact that the instruments made a slight puncture in the skin and for the rest pushed the tissues aside rather than cut them. Suppuration of the wounds was unknown despite the filthy conditions in which the instruments were kept. In the subsequent discussion some wartime experiences were related in which the victim of a severe wound although fully conscious was not aware of his condition until told of it. It was suggested that the booming of the guns had the same hypnotical effect as the continual drumming in the dervish dances. With regard to fakirs' tricks Dr Hunt mentioned that the late Lieutenant-Colonel R H Elliot from his experience of thirty years in India had declared that none of the fakir performances could be explained without ascribing supernatural powers. The various trick of the mango tree which grew before the astonished eyes of the audience said Dr Hunt, was pure conjuring the conjurer diverting the attention of his audience while he substituted larger plants from under his cloak. The rope trick had never been performed in the open with an ordinary rope but only under a tree where there was a boy in the branches to catch it when it was thrown.

We regret to announce the deaths of Surgeon Vice Admiral Sir Robert Hill KCB who was Principal Medical Officer with the Grand Fleet 1916-19 and Medical Director General RN 1919-23 and of Mr J Bright Banister osteo-physician to Charing Cross Hospital surgeon to the Chelsea Hospital for Women and consulting obstetric surgeon to Queen Charlotte's Maternity Hospital.

# SURGICAL PROCEDURES IN GENERAL PRACTICE

*This is one of a series of articles contributed by invitation*

## INJURIES AND INFECTIONS OF THE EYE

BY

ARNOLD SORSBY, F.R.C.S

Diagnosis and treatment of the minor injuries and infections of the eye and eyelids do not call for the specialized knowledge and methods that major ophthalmology requires, but minor ophthalmology does none the less necessitate something of the same faithfulness to detail and care in examination. These are acquirements not beyond the reach of the conscientious practitioner. Since the complicated ritual of "inspection, palpation, percussion, and auscultation" is replaced in ophthalmology almost entirely by inspection, the first essential in the treatment of eye conditions—the minor no less than the major—is facility in the use of the inspection lamp, the condensing lens, and the loupe. That amaurosis which has been defined as the condition in which the patient saw nothing and the doctor also saw nothing most definitely has no place in modern ophthalmology. To undertake the diagnosis of an eye lesion without the aid of suitable illumination is folly, to attempt treatment under such conditions borders on malpractice. Equipped with an irreducible minimum of special information, an average of general knowledge, and the maximum of suitable conditions in the way of illumination, minor ophthalmology falls well within the province of the general practitioner.

### Foreign Bodies

The conjunctival sac is a self-flushing mechanism, so that most foreign bodies are washed away automatically, this being helped by the excessive flow of tears caused by the irritation from the foreign body. It is only when a foreign body becomes embedded that mechanical removal is called for. The simplest mechanical procedure, one which works quite well in a large proportion of cases of foreign bodies lightly fixed on to the cornea, is to pull the upper lid on to the cornea and by a few brisk vertical and lateral movements of the lid set the foreign body free. Once it floats freely in the conjunctival sac it is usually washed away. When a foreign body is more firmly embedded in the cornea instrumental removal becomes necessary. The eye should be anaesthetized by the instillation of two or three drops of 4 per cent cocaine solution, repeated after an interval of two minutes. Whilst the cocaine is exerting its action the eye should be kept closed. When the eye is fully anaesthetized an assistant should keep the lid open the patient being instructed to open the unaffected eye. It is also the duty of the assistant to concentrate the light on to the cornea, using a condensing lens if necessary. Having located the foreign body with the naked eye when it is fairly large, or with the aid of the loupe when it is small the operator should proceed to dislodge it by introducing a dissection needle behind it. The widespread practice of scratching the foreign body away with a flat spud should not be employed, it is a crude procedure which does not dislodge any firmly embedded foreign body, and it damages the corneal epithelium over a large surface, producing an abrasion. The use of the dissection needle is easily acquired, and the one important

thing to remember is that manipulations with a fine point should be in a plane parallel to the cornea and not at right angles to it, as otherwise the cornea may be perforated, with dire consequences. Foreign bodies that have been embedded for a day or so generally leave some discoloration of the bed. Unless one is expert at removing tiny particles it is better to leave that alone. The instillation of some antiseptic drops, such as gutt. emul. o. acriflavin 1 in 2,000, or gutt. coll. argentum 1 in 2,000 or gutt. argyrol 10 per cent, after a foreign body has been removed, is useful. As the cornea remains anaesthetized for several hours it is essential to bandage the eye after this procedure.

Foreign bodies giving trouble are not necessarily always on the cornea. Occasionally much discomfort is experienced from the lodgment of a foreign body, sometimes of surprising dimensions, in the fornix of the upper lid. No search is therefore complete if it only involves inspection of the cornea. The lower fornix is easily seen, and the upper lid must be turned out with due pressure on the fornix to disclose its folds. Foreign bodies of this type are generally quite easily removed with a pledget of cotton-wool, cocaineization of the eye not often being called for.

### Corneal Abrasion

A baby's finger poked into an eye is a common cause of corneal abrasion, scratching of the cornea by other means is relatively uncommon, if one excludes unskilled attempts to remove foreign bodies. Spontaneous abrasions may sometimes occur as a familial corneal lesion. Abrasions are never silent lesions—they produce extreme irritability, and advice is invariably sought. The irritability does not subside until the epithelium covering the exposed nerve terminals is healed again. The discomfort can be alleviated by the instillation of a mydriatic such as atropine 1 per cent in all patients under 40 and in the over 40 who have normal ocular tension, in addition a pad and bandage should be placed over the eye. In most cases the symptoms subside within three or four days, though they may persist for as long as a week.

### Corneal Ulcerations

Trauma is responsible for a large proportion of corneal ulcers. An unremoved foreign body, an infected abrasion, and traumatic loss of tissue can cause a corneal ulcer. The treatment of a corneal ulcer depends entirely upon whether the ulcer is infected or not. The uninfected ulcer has a clean base and clean margins. The infected ulcer has a yellowish or dirty greyish appearance, usually most pronounced at the margins. An uninfected ulcer is treated in the same way as a corneal abrasion. Indeed, there is little difference between an abrasion and a corneal ulcer in the one the epithelium only is concerned, in the other interstitial tissue is also involved. Where infection has occurred serious consequences may result, even to the extent of the whole of the cornea being destroyed. The sepsis must be combated energetically, and most corneal ulcers respond well to carbolic acid. This is a simple procedure, as follows:

(a) The extent of the ulcer is clearly defined by painting out with two drops of watery fluorescein 1 per cent solution.

into the conjunctival sac and washed away with two drops of cocaine 4 per cent the excess fluid being drawn off with clean blotting paper.

(b) The ulcerated area thus marked out is then lightly touched with pure liquefied carbolic acid applied with a match cut down at one end to a fine point which is soaked in the carbolic acid. The amount of acid actually brought in contact with the ulcerated surface and the infected margins is therefore very small. If an excess of carbolic acid has been applied it forms a greyish film on the healthy epithelium; this should of course be avoided but no serious consequences result from the presence of a minute drop of carbolic on the healthy cornea. Special care should be taken with the margins particularly in the case of a spreading ulcer.

(c) The carbolic acid acts as an analgesic as well as an antiseptic but the procedure is none the less painful; the pain often being more intense an hour after the carbolizing than during the process itself. The discomfort can be alleviated by instilling pure castor oil drops into the conjunctival sac and bandaging the eye though bandages should never be applied where there is a mucopurulent discharge. Symptomatic treatment for the pain such as the administration of aspirin, phenacetin etc. may be necessary. If a corneal ulcer does not respond to carbolizing the matter becomes an emergency to be left to an expert for at its best a corneal scar seriously affects vision. Carbolicizing can be repeated at daily intervals but excessive carbolizing is to be deprecated.

#### Industrial Accidents

Many cases of foreign bodies in the eye abrasions and corneal ulcers are industrial accidents. These occur with far too great a frequency for though excellent protective measures are now available they are unfortunately not widely used. Protective goggles that can be comfortably worn have been devised to overcome the special dangers to which workmen exposed to flying chips of stone and metal are liable. The Home Office Industrial Museum has a large collection of such appliances and the example of the Royal Eye Hospital London where there is a permanent exhibition of different types of goggles and special protective appliances might well be copied by other ophthalmic centres. Industrial accidents are not confined to minor injuries; intra ocular foreign bodies are not uncommon and when they do not lead to the loss of the eye they often seriously lower the visual capacity and limit the industrial efficiency of the victim. Every perforating wound of the eye and every case in which an intra ocular foreign body is suspected should at once be referred to a properly equipped ophthalmic department. Radiant energy is also a factor in industrial injuries with a range extending from transient conjunctivitis to cataract formation. These conditions too are largely preventable by the use of suitable goggles.

#### Styes

An isolated styne calls for no further treatment than the epilation of one or more infected lashes together with hot fomentations. Incision of a styne should be avoided. A spreading crop of styes from the infection of adjacent hair follicles is not infrequent and makes treatment of the condition tedious. When multiple infection occurs rational treatment aims at increasing the patient's resistance. In addition a course of colloidal manganese injections is sometimes helpful 1 ccm being injected intramuscularly at weekly intervals for six weeks.

#### Blepharitis

Blepharitis is essentially a disease of childhood. It would appear that there is no local exciting factor but any refractive error present should be corrected. The milder forms of blepharitis respond to washing away of the crusts with bicarbonate solution 20 grains to the

ounce. The lid margins are best washed by means of pledgets of cotton wool soaked in the solution and this should be done at night and in the morning. More severe cases require the washing off of the crusts with pledgets of cotton wool soaked in hydrogen peroxide 10 or 20 volumes and painting the lid margins with liquoratorium B.P.C. every night. This treatment has the advantage of imparting a bluish colour to the lid margin but it is far more efficacious than the measures usually adopted. It has proved singularly successful at White Oak Hospital where the severest cases of blepharitis in London school children are treated. The general factor of blepharitis must not be overlooked; the children affected are often undernourished and attention to their general health is essential.

#### Phlyctenular Ophthalmia

In contrast to the exogenous type of phlyctenular ophthalmia sent by the traumatic ulcer the endogenous type is that is endogenous in origin. Phlyctenular ophthalmia represents one of the commoner types. While phlyctenular conjunctivitis causes much discomfort, it is not a sign of the intense photophobia and corneal involvement is a grave complication not only because the symptoms are much more intense but also because of the sequelae in the form of corneal scarring. In view of the liability to frequent relapses phlyctenular ophthalmia should be regarded as a condition calling for an intensive examination of the child. In practically all cases evidence of tuberculous infection as shown by the Mantoux test will be found, though active clinical tuberculosis is the exception. Phlyctenular may indeed be regarded as a sporadic tubercular reaction in the cornea of a tuberculous child and every care is to be taken to eliminate contact with tuberculous patients. The general health of the child calls for attention and a prolonged stay in the country is indicated particularly in cases in which the cornea is involved. At the height of an attack much can be done to make the child more comfortable. Protection against light can be given by the use of dark glasses supplemented if necessary by a double shade over the eyes. These shades should be home made the material used being some flexible cardboard the shades generally sold do not readily allow discharge to drain away from the eye and are often pained with irritating dust. Where the cornea is involved gutta atropin 1 per cent 2 drops thrice daily should be instilled in the affected eye. Various vitamin preparations as also cod liver oil have been recommended as specifics they are useful in so far as they help to build up the patient. The child with phlyctenular ophthalmia should be regarded as a potential victim of clinical tuberculosis and the general lines of treatment for this type of patient are more important than a narrow adherence to some special medication. Where the corneal complications of phlyctenular ophthalmia consist of relatively evanescent vesicles which break down leaving a small ulcer that heals readily local applications other than atropine drops are to be avoided. The scarring that corneal phlyctenulae leave tends to become less marked with time where the scarring is heavy restoration to the normal is helped by the use of ethylmorphine hydrochloride ("diormin"). This in solution should be instilled into the eye when all signs of irritability have been abated for at least four weeks the strength being increased up from 2 per cent to 3 per cent increasing to 1 per cent at fortnightly intervals. The drops should be used once a day only preferably in the evening and as they are irritating they should be discontinued at the first sign of irritation of the eye.

### Rosacea Keratitis

In contrast to phlyctenular keratitis with its heavy incidence in children, rosacea keratitis is essentially an affection of youngish women suffering from acne rosacea. The corneal lesion may be present when the skin condition is in abeyance, and this affection is to be suspected in cases of recurrent corneal ulceration in women 20 to 30 years of age. Gutt atropin 1 per cent, 2 drops twice daily in the affected eye and dark glasses if necessary, constitute the local treatment where ulceration is active. Of greater importance is the adjustment of any alimentary disorder that may be present. Generally a mixture containing 15 to 20 minims of dilute hydrochloric acid taken by mouth three times a day proves most helpful as hypochlorhydria is commonly present.

## THE CANCER CAMPAIGN

Viscount Hailsham presided at the sixty-sixth quarterly meeting of the Grand Council of the British Empire Cancer Campaign held at 11, Grosvenor Crescent, S.W., on April 11. Those present included Lady Barrett, Mr Stantford Cade, Dr Malcolm Donaldson, Sir Charles Gordon-Watson, Mr W Sampson Handley, Dr G W C Kaye, Professor J McIntosh, Mr W Ernest Miles, Mr W H Ogilvie, Mr Cecil Rowntree, Mr R H Jocelyn Swan, Sir James Walton, Sir David Wilkie, and Dr R W Scarff (honorary secretary of the Scientific Committees).

A further sum of £1,338 was allotted for one year for the extension of the national propaganda work being carried out by the Central Propaganda Committee. The committee will now proceed to arrange these free educational lectures in Cornwall, Devon, Dorset, Gloucestershire, Somerset, Wiltshire, and also in South Wales. Dr Malcolm Donaldson, the chairman of the committee, reported that to date over 700 public lectures had been given in the fifteen English counties which have already been organized. A report was received from the Co-ordinating Committee, which represents headquarters and the principal autonomous provincial councils of the Campaign concerning the production of a propaganda film to be used in conjunction with the educational lecture schemes. It was unanimously decided that such a film should be produced by the Central Propaganda Committee in collaboration with the autonomous councils.

### Investigations in Progress

Sir Charles Gordon Watson, vice-chairman of the Clinical Cancer Research Committee reported that the organization for the statistical cancer inquiries in the teaching and special hospitals of London and the hospitals of the London County Council and the Middlesex County Council had now been completed. All these institutions had appointed registrars to take charge of the records at their respective hospitals and the headquarters arrangements were being perfected to deal with the data concerning over 17,000 new cases of cancer yearly in the metropolitan area of London. Grand Council confirmed the recommendation for the appointment in the near future of a full-time medical secretary and registrar at headquarters for this purpose.

A further grant of £1,000 for one year was placed at the disposal of the North of England Council of the Campaign to enable the short wave investigations to be continued under the direction of Dr F Dickens and Dr S F Evans. This work, which is a continuation of that which appeared in the last annual report of the Campaign and in a recent issue of the *American Journal of Cancer* concerns the investigation of the effect of varying forms of heat upon malignant tissues.

### Early Diagnosis and Treatment of Cancer

The incidence, prevention, and treatment of cancer was discussed by Sir Arthur MacNalty, Chief Medical Officer of the Ministry of Health, in an address delivered on the following day at a meeting of the British Empire Cancer Campaign at the Mansion House. The Lord Mayor of London, who presided, explained that the Minister of Health, who was to have delivered the address had been detained by business in the House of Commons.

Sir Arthur MacNalty said that, although cancer had now risen to second place in the list of fatal diseases in this country, it did not necessarily follow that the causes of the disease, whatever they might be, were becoming more prevalent. Increasing longevity (to day people lived on the average, fifteen years longer than they did a generation ago), increased ability to diagnose cancer in difficult cases, and true certification of the causes of death all played a part. The main lines of attack on the disease were prevention and treatment. On the side of prevention it could be said that the study of the causes of cancer was being carried on with great vigour throughout the world, and the boundaries of knowledge had been considerably extended.

In the realm of diagnosis and treatment radium and x rays were now associated with surgery, and the large hospitals of the country were now supplied with facilities for treatment by radium. Excluding London, there were at present in Great Britain twenty-two radium centres of which seventeen were in England, one in Wales and four in Scotland. The chief national concern was clearly that facilities for early diagnosis and adequate treatment should be readily available to the whole population. That adequate facilities were still far from being readily available appeared from investigations made by the Radium Commission and in the Ministry of Health. The problem was to ascertain how a small number of hospitals specially equipped with radiation plant might serve the whole population, in other words, these hospitals should serve for the purposes of cancer, areas larger than those they normally served. The extension of the sphere of influence of such hospitals and the creation of more treatment centres both offered possibilities as means of approach to the problem, but whatever arrangements were adopted it was evident that to throw a burden of this national kind wholly upon a small number of hospitals would be impracticable.

### Need for Joint Efforts

The Minister of Health felt satisfied, and was supported by the views of the Radium Commission, that the position could best be met, and indeed could only be met, by more active co-operation on the part of local authorities. Broadly speaking, the division of function between voluntary hospitals containing treatment centres and local authorities would be that treatment would remain with, and be carried on in, the hospitals (the "centres"), while the peripheral "field" work would rest with the local authorities. Another important work was that of bringing to the notice of the public and of medical practitioners the provision of additional facilities. The Propaganda Committee of the British Empire Cancer Campaign had done good work in this connection and a wider provision for diagnosis and treatment should enable more people to follow the advice, "Go and see your doctor without delay."

"The general view of the situation," concluded Sir Arthur MacNalty, "is that, even though the results of research may eventually put into our hands one or more means of prevention, their effects cannot be expected to be immediate and striking. Until those effects can be fulfilled we must expect the usual incidence of cancer and consequently provision of means for diagnosis and treatment cannot be regarded as other than essential."

## CRIME AND CRIMINALS

## STATISTICS FOR 1936

One reflection prompted by a study of the *Criminal Statistics 1936*<sup>1</sup> is the small proportion of all crime that is really serious. In 1936 the total number of persons found guilty of offences of all kinds was about 825,000. Of these over 99 per cent were dealt with by magistrates and under 1 per cent were tried by jury. Nearly 60 per cent had committed traffic offences. Nine per cent had committed indictable offences of which the great majority were thefts and the remainder had misbehaved themselves in various non indictable ways—for example drunkenness, failure to take out dog licences and Sunday trading. Of all these offenders 81 per cent were fined, 10 per cent were dismissed with a caution, 5 per cent were bound over (3 per cent being put on probation) and 3 per cent were sent to prison or Borstal. The figure for traffic offences was 13 per cent higher than in 1935. The curve is rising steadily but so is that of the total number of vehicles on the road. From 1920 to 1932 there was a continuous decline in the number of persons convicted of drunkenness, since 1932 there has been a continuous increase. It is permissible to speculate whether this is not part of the increasing tendency towards insecurity, pessimism, and chaos which is showing itself in various forms all over the world. On the other hand the figures for non indictable assault have shown a steady fall since 1931. Eight times as many males commit indictable offences as females and the incidence of crime is highest under 14 and drops steadily with the advance in age.

## Young Offenders

The increase in crime among persons under 17 continues but the rise in 1936 was not nearly so great as in 1935—possibly because the population as a whole is settling down to the operation of the Children and Young Persons Act, 1933. This Act with its provision for the optimistic treatment of young offenders probably induced many more persons to prosecute children and young persons than would have done so before. The figures show wide discrepancies between the different districts in the use of probation for persons over 17. The percentage for the whole country of adult offenders placed on probation was 19.1. In the Metropolitan police district it was 29, in Hertfordshire 50, in Bradford 45 and in Nottingham City 40. In Liverpool the percentage was only 10, in Manchester 12 and in Leeds 14. In the West Riding of Yorkshire it was 7 and in Durham County 6. In Bristol it rose during 1936 to 21 from 12.8 the year before and in Glamorgan it rose from 4.8 in 1935 to 10.1 in 1936. Of the juveniles found guilty of indictable offences 48 per cent were placed on probation.

The police of course know of more crimes than are proved in court partly because the offender either cannot be detected or for some reason cannot be prosecuted or because he admits former offences in order that they may be taken into consideration when he is being sentenced for another offence. In 1936 the police knew of over 176,000 larcenies against 165,000 in 1935. They knew of over 38,000 cases of breaking and entering against 26,000 in 1935. These figures include a large number of minor crimes. The value of the property stolen in 180,000 cases of theft was under £5 in 79 per cent and over £100 in only 1.3 per cent. The number of sexual offences known to the police was 4,358 against 3,835 the year before and the number of cases of violence against the person 2,545 compared with 2,431. In 1926 the police knew of 99 cases of murder of 112 victims over one year old. In 33 cases the murderer or suspect committed suicide. In 61 cases 64 persons were arrested in five cases no arrest

was made. Of these 64 prisoners eleven were found insane on arraignment and fifteen were found guilty and insane after trial. Ten were acquitted and 23 were convicted. Of these two were certified insane, thirteen were reprimanded and sent to penal servitude and only eight were executed. The remainder died before trial, were rescued abroad or were discharged at the police court.

## Growing Incidence of Suicide

Five thousand persons committed suicide and over 200 cases of attempted suicide came to the knowledge of the police. The steady growth in the incidence of suicide which has been noted since 1921 is accounted for at the Home Office by the increase that has taken place in the higher age groups of the population for the number of suicides occur in the higher age groups. Among men under 55 the suicide rate was 10.6 in 1936, than in 1911, among men over 55 it was 11.1. Among girls and women under 25 it was 10.1, than in 1911, among women between 25 and 45 it was 11.1, higher and among women over 45 it was 10.1, higher. The Home Payments Act 1933 has had an effect which was hoped of decreasing the number of persons committed to prison for debt and for other reasons sums due from them—for example from men in the orders of affiliation and rates.

## SCIENCE IN MODERN LIFE

## WORK OF THE N.P.L.

The National Physical Laboratory is by no means a aloof scientific institution. Its work as its name implies testifies is closely related to the needs of the man in the street—literally in the street because among the major matters referred to in the present report are the lighting of streets and street noises. A prolonged investigation is taking place in order to ascertain the advantages of lighting schemes or different colours for enabling persons and objects to be picked out on the roads at night.

## The Control of Noise

As for street noises tests in which two hundred persons have assisted have been carried out to decide what sound emitted by a motor horn may be called a warning without assaulting the nerve. It is recommended that the sound should not exceed 140 phons, the phon being the unit of equivalent loudness recommended by the British Standards Institution. The motor horn may be another noise nuisance on the road. Here owing to the lack of noise measuring apparatus and in all this work measurement comes first and afterwards rectification—the silencing of motor cycles has not been uniformly carried out. A new investigation of the problems of both exhaust and mechanical noise has been started at the Laboratory using the accurate noise meters and analysers which have now been developed and it is hoped that the information obtained will enable improved silencers to be designed for the various types of machinery in use. The London Passenger Transport Board has also requested the assistance of the Laboratory with a view to the reduction of the noise of tube trains. The noise emitted by aircraft at high speed is becoming a serious nuisance and as air raid precautions appear to be a part of our daily existence it is just as well that the Laboratory should be placing on a scientific basis the sounds emitted by sirens and maroons.

In a noisy world the authorities at Teddington are doing their best to discover the out-pedal words from outside noises of a passing nature are the words which are com-

<sup>1</sup> Cmd 5690 H.M. Stationery Office 1938 35 6d

pelled to live with indoors, especially with the increasing habit of people in cities to live on the top of one another. The transmission of sound through walls and floors has been studied, and architects have been assisted in the designing of silent buildings. Possibly in flats the source of greatest irritation is the conduction of sound along water pipes and it has been found that by inserting short lengths of rubber hose in the pipes this trouble can be eliminated. A large amount of work remains to be done not only in the suppression of sounds we do not want to hear but in the better transmission of sounds that we do. The acoustics of public halls is far from perfect, as witness the frequent difficulty in hearing and the hasty improvisations at Annual Representative Meetings of the B.M.A. Microphones and amplifiers sometimes make matters worse instead of better. We have known a microphone set up such interference in its vicinity that it was impossible to hear the speaker a yard away, while a hundred yards away his voice rolled like thunder. Workers from the Laboratory have been engaged during the year in advising on the acoustical properties, now said to be perfect of what is probably the most magnificent assembly hall in the world—that of the new League of Nations building at Geneva. A pity if, having got it perfect acoustically, no sounds should be heard there save the echoes of a mausoleum!

#### Direct Services to Medicine

In two other directions of interest to medicine the Laboratory has lately done good service. It was the publication of its work on the measurement of gamma ray dosage which influenced the important decision at Chicago last September by the International Committee on Radiological Units to generalize the definition of the "roentgen"—the unit of x-ray quantity—to include gamma radiation. The employment of gamma rays of radium independently of or in conjunction with x-rays makes it desirable that both kinds of radiation should be measured in terms of the same unit, and the use of the same unit of quantity has been shown to be practicable. When the "roentgen" was introduced ten years ago the maximum voltage used in x-ray treatment was of the order of 200 kilovolts. Nowadays much higher voltages are used and it is important that satisfactory measurements of quantity should still be possible.

The other matter relates to the risk of explosion of anaesthetic vapours as a result of sparks arising from static electrification in operating theatres. Experiments have shown that it is possible by the movement of blankets and the like to produce electrification of sufficient intensity to give rise to a spark capable of igniting the mixtures of gases and vapours commonly used for anaesthetic purposes. Possible methods of avoiding this risk have been studied and the provision of earthing chains trailing from operating tables, trolleys and other equipment on to a semi-conducting floor is recommended while the use of the partially conducting rubber now available promises to be of value.

An international postgraduate course in malariology will be held in Rome from July 18 to September 17. The language used will be French and many interpreters will be available for those taking part in it. The fee payable is 1,500 lire and this sum must be received before June 20. The aspects of malaria to be dealt with include haematology of the disease, protozoology, microscopical diagnosis, the pathological anatomy and clinical considerations, entomology, epidemiology, prophylaxis, field work, malariatherapy from the psychiatric point of view, laboratory work and a visit to a clinic. Excursions in connexion with this course will be made to various sanitary stations near Rome, Ostia, Venice and Sardinia. Further details may be obtained from Professor G. Bastianelli, Istituto di Malariologia, Ettore Marchisio, Policlinico Umberto I, Rome.

## Reports of Societies

### AIR RAID PRECAUTIONS ORGANIZATION OF MEDICAL SERVICES

At a meeting of the United Services Section of the Royal Society of Medicine on April 11, Colonel A. G. BIGGAM presiding, a paper was read by Colonel E. M. COWELL on the organization of medical services in air raid precautions.

Colonel Cowell explained that the suggestions he had to put forward were made after three and a half years' experience in a casualty clearing station in France during the great war and nearly four years' work as Red Cross organizing officer in Surrey in connexion with the air raid precautions scheme. Practically every 'civilized' country in the world was preparing to defend its civil population against air warfare, including gas. He showed some interesting posters issued by the Soviet Government. In Paris a large number of underground shelters had already been erected, including first-aid posts which were practically hospitals of considerable size. In Berlin a first aid post was organized at each of the 200 police sub-stations. Something was to be learned from the war in Spain, where, however, gas had not been used. In eighteen raids on Barcelona—earlier than the continuous raiding which took place in the middle of March—over a period of two months 100-lb. bombs were chiefly used and the total casualties were said to be 700 killed and 700 wounded.

All European countries, except perhaps Turkey, could attack these islands by air. The modern high speed bomber could fly at a height of 20,000 feet and at a speed of 200 or more miles per hour, carrying four or five 500-lb. bombs. A formation of thirty-six machines, attacking a given locality, dropping a ton of bombs in an area with a population of from 30,000 to 50,000 per square mile, might be expected to cause 1,000 casualties by night or 2,000 by day. The ratio of killed to wounded was likely to vary from 1:1 to 1:2, and the proportion of walking to lying casualties might be taken roughly as 2:1, but half the "walking" cases would require sitting transport. With regard to gas casualties many uncertain factors such as weather conditions would come into play. Estimates of what was required to gas a big city had been made, the figures were such that the gassing of a capital might be regarded as practically impossible. He also gave some figures for possible casualties from incendiary bombs, and pointed out that the uncertainty of the locality to be attacked and the absence of warning made it imperative that medical units should be mobilized everywhere, and some units which would not be actually engaged must be mobile enough to reinforce the units in less favoured localities.

#### Medical Personnel

In considering the organization of the medical services Colonel Cowell emphasized the need for the appointment of surgical and medical consultants in time to assist in the training of volunteer surgeons and physicians, anaesthetists, and general duty practitioners. The Air Raid Precautions organization was the greatest task ever imposed on this country, and up to the present practically a voluntary one. In densely populated areas a percentage of 1:30 of the population must be found and trained for medical purposes only a personnel of 1:100. The medical personnel approximately 1 in 25 should be doctors. Dental surgeons would be useful in organization, some to act as assistants to operating surgeons, others, after a little extra training as medical students in their final year, should be called upon in exactly the same way. In the early days of the services of Territorial troops might be called upon, the local authority, and steps should be taken to

familiarize them with the use of protective clothing and the handling of stretchers. As many of the civilian casualties might be women and children, more easily handled than men, a certain number of women might be trained in this duty.

The collection of casualties would probably have to be done in darkness. After the rescue parties had brought the casualties out of damaged buildings the duties of the medical personnel would begin. A stretcher party would need a stretcher in an oilskin cover, a blanket, a surgical haversack and spare respirators. Colonel Cowell suggested that the criss used by stretcher parties should have a zip fastener and should contain triangular bandages, shell dressings, splints, tourniquets, scissors and safety pins also labels for priority cases, an electric torch and a notebook for messages. In towns where large numbers of casualties might occur it would be advisable to send all the walking and some of the lying cases to the first aid post and certain of the lying cases to the casualty clearing hospital direct, the dead being taken to a central mortuary. Motor ambulances should be stationed two at each first aid post, two at the casualty clearing station, four at headquarters in reserve and three, for evacuation at each of the base hospitals.

A certain number of slightly wounded and gassed cases would make their way home and call in their own doctor. With this fact in mind appeals had been made by the Home Office and the British Medical Association for doctors to study the treatment of gas casualties. Private practice, however, would be uneconomical in manpower; large numbers of doctors would be required to serve with the medical units and it was hoped that the medical profession would collaborate with the local authorities and volunteer their services for this organized effort.

#### Selection of Buildings

For first aid posts schools were convenient and in view of gas cases the necessary alterations, including the provision of bathing rooms should be taken in hand. It would not be possible to render existing buildings entirely proof against bombs, splinters, fire and gas, but attempts should be made to do the best possible in the circumstances. Where practicable sufficient 6 ft trenches should be dug in the immediate vicinity, these if rooted and covered with sandbags would afford some protection for patients who could walk. Where new hospital or school buildings were being erected the ceilings of the ground floor should be made strong enough to carry the structure above and include a 12-in layer of concrete. The roof if tiled or slated could easily be pierced by thermite bombs. To prevent fires the attic floors should be covered by a layer of concrete slabs.

First aid posts should be large enough to accommodate 300 patients—100 lying and 200 walking. The personnel of the first aid post should be fifty, including twenty-five nursing orderlies. In Colonel Cowell's opinion the presence of a doctor at the first aid post was essential. He would sustain the morale of the patients, diagnose doubtful cases, give priority to urgent ones, perform immediate operations required to save life and exercise general supervision over the medical work.

As to the casualty clearing hospital, tents or huts were undoubtedly ideal but it was difficult to render these gas-proof and existing buildings would in most cases be chosen. Probably in future wars forward medical units would best protect themselves by camouflage. At the heights at which aeroplanes might now fly, signs would be indistinguishable. The forthcoming International Red Cross Congress in London was to consider the question of securing recognition of neutralized hospital areas or *villes sanitaires*.

The casualty clearing hospital was the most important unit in the medical organization. One such hospital was required for 100,000 population. It should accommodate 200 cases, seventy-five only of these to be in beds, the

remainder on cots or stretchers. The hospitals should be in groups of two, three or four. The officer in charge should be a doctor with an assistant or deputy for night duty. The personnel per unit should be ten medical officers, twenty nurses, three duty officers, thirty nursing orderlies and others bringing the total voluntary personnel to eighty. In such a hospital 100 lying cases could be dealt with by six teams in eight hours. The treatment room should be large enough for eight stretchers and for sitting cases. The best results would be obtained with teams of seven persons—surgeon, anaesthetist, six stretcher orderlies and two stretcher bearers. The use of a portable system was advocated, whereby two tables per team allowed the second case to be prepared for operation while the first operation was being completed. The mobile operating theatre rushing to a casualty on a stretcher and operating on the spot, appealed to the imagination, but it was bad for the patient and hardly to be recommended. The surgical maxim must remain: Efficient first aid and rapid evacuation.

Finally the base hospital should be as far removed as possible from any definite target. In general terms it would approximate closely to an ordinary civil hospital. Accommodation for 1,000 casualties per 100,000 population might be required, but all localities would not be attacked at once and one hospital would be available. The work of the doctors at the first aid posts and casualty clearing hospitals would only be of short duration; raids would not last continually day after day and therefore the would be able to attend the base hospital. Here as in every part of the organization Colonel Cowell gave details of the personnel and accommodation required and concluded with a time table of performance of medical units in an imagined air raid on a concentrated population.

#### General Discussion

Air Commodore W. TYSSELL said that in a country became a target for attack the responsibility would have to be on national lines. The arrangements should be centrally co-ordinated on basic principles which could be applied to civilian emergencies equally in Navy, Army or Air Force emergencies. This meant a uniformity in the terminology, procedure and technique given in textbooks. If ordinary administrative instructions and from a co-ordinated policy were centralized and then applied with sufficient elasticity to allow for modification to suit local or defence force circumstances it would be of considerable help in dealing with panic—the first element in all bombing and gas attacks. The arrangements for evacuation, treatment and disposal of casualties should be based on the assumption that casualties would only be in a forward area and that once they had been placed on to clearing stations they were relatively safe. But in the event there would be no relative safety and therefore it would be necessary to provide in every part of the country arrangements for collection; this was being done by the Home Office. It was in the case of the co-incident destruction of a first aid post and a clearing hospital that Colonel Cowell suggested co-operation and co-ordination would come in where another area would be requisitioned for help. This emphasized the need for central co-ordination in the first place, then centralization through central channels. Yet another problem was how to overcome the apparent incompatibility of treatment, shock and collapse and decontaminating the patient. This applied particularly to mustard gas. The protection of hospitals against proved mustard gas was a problem that needed solution.

Dr J. N. DOBBIE (London County Council) said that the term casualty clearing hospital was a misnomer, as each first aid post and clearing hospital would be in the front rank. Hospitals would have to be established out of London. He suggested tent or huts in a building district. There might be established under the National Fireworks Campaign as holiday camps and hostels or huts and turned into the other use it and when the need arose. School buildings did not lend themselves to conversion into hospitals.

Dr DONALD STEWART (Imperial Chemical Industries) said that he had been called upon to arrange medical services to deal with possible casualties among factory workers in the Midlands and although the relevant Home Office publications were helpful when it came to the accurate disposition of personnel he found little apart from R A M C training, which was of help. The problem of rehabilitation and return to work of those persons who might be injured in an air raid was one that should be considered now as part of the whole scheme. It took several years of war after 1914 to evolve satisfactory schemes for rehabilitation and to make traumatic war surgery a definite entity. To deal with the problem these emergency measures had to be put into force, and these measures had a most significant bearing on the present day problem of treatment and rehabilitation in general. Dr Stewart suggested that thought should be given to this subject now and the practical application of the rules which were worked out during the years 1914-19, and the lessons then learned should be seriously reconsidered by the medical profession. One other point concerned the wearing of protective clothing. Recently he had seen a number of strong healthy men taking part in decontamination and anti gas measures who were wearing this clothing and found themselves quite unfit to carry on for longer than a few minutes. On this same matter of gas-proof clothing Surgeon Commander S G RAINSFORD said that the Admiralty carried out an investigation some years ago and were surprised at the length of time the men could work.

Group Captain STRUAN MARSHALL drew attention to the 'contra-gas tent'—an oilskin tent impervious from the outside and containing a small oxygen apparatus. Being soft-walled this tent could stand a great amount of blast without breaking. Dr D W WALKER referred to the need for all medical officers to be trained in anti-gas treatment. It was not always easy to secure such training.

Colonel COWELL in reply said that his paper would appear in full in the *Journal of the R A M C*. The question of the provision and co-ordination of a central staff was very important, and he hoped much would be done in that way shortly. It was felt that each local authority knew its own difficulties and could provide its own organization but with regard to medical services there must be co-ordination with neighbouring authorities under central control. He agreed that allowance must be made for medical units themselves becoming casualties. With regard to admission to hospitals if serious cases were sent straight to the casualty clearing hospitals these would be swamped, by using dressing stations first cases could be fed to clearing hospitals as arrangements were made. Territorial London general hospitals were not in London, No 2 was at Epsom and No 5 at Orpington. He added that most local authorities had developed a conscience in this matter of air raid precautions. He had worked at it in Surrey for three and a half years and had organized a personnel of 10 000 for the Red Cross. It was not difficult to get people to begin with, the difficulty was to keep up their interest.

### JUVENILE NERVOUS AND MENTAL INSTABILITY

A meeting of the Liverpool Medical Institution was held on March 17 with the president Dr E GILBERT BARK in the chair. Dr MURIEL BARTON HALL read a paper on juvenile nervous and mental instability, based upon records of 1 000 consecutive cases of young persons in the second decade of life.

Dr Hall said these cases were examined between 1924 and 1937. Nearly half (496) were seen at the Liverpool psychiatric clinic, opened in May 1924, 186 were seen at the Liverpool child guidance clinic, opened in November, 1929, 139 were seen in the department of psychological medicine of the Liverpool Royal Infirmary, opened in 1930 the remainder (179) were cases from her private practice. The series included every case of a boy or girl

who was aged not less than 10 or more than 19 who had first examined, 387 patients were under 15, 613 were over 15. Unselected in any way, the condition connected to the cases was that by those who referred them in the course of ordinary practice all were considered suitable to be dealt with by a medical psychologist. There were 554 girls and 417 boys, with the exception of one girl who was unmarried. The cases were referred for investigation and treatment from three main sources:

- 1 General practitioners, consultants and specialists 431
- 2 Social organizations concerned with the moral and physical welfare of young people 376
- 3 Public authorities, including school medical officers, public health officers, Home Office and police court officials 192

Each case was recorded in detail according to a prepared system, which included a record of the family and personal histories and of physical and mental examinations and a statement regarding the diagnosis and prognosis arrived at and the recommendations made. The personal history included details of birth, early development, physical health, school progress, general conduct, environment and difficulties or changes, and occupations followed. Each patient underwent a general physical examination in which particular attention was paid to the central nervous, endocrine, and allied systems, a mental examination was conducted in every case. Where necessary, and this included the majority of cases, detailed psychometric examination of intellectual development and powers was undertaken. The chief purposes of the investigation, however, were those of arriving at a diagnosis, recording a prognosis, making recommendations concerning treatment and instituting a system whereby each case could be followed up at subsequent intervals for the purpose of checking the two former and noting whether the recommendations had been put into practice and, if so, with what result. The cases referred comprised 515, in which disorders of conduct varying from laziness, violent temper, and pilfering to truancy, stealing, vagrancy, and forgery were the prominent symptoms, 448 in which nervous symptoms including fears, obsessions, dreads, depressions, stammering, and enuresis were noted, and thirty seven in which the outstanding difficulty was an educational problem such as backwardness in school work or failure in competitive examinations.

### Aetiological Factors

The main aetiological factors explored were those of (i) heredity, (ii) intellect, and (iii) home environment. A psychopathic family history was found to be present in 56 per cent of cases. A positive finding was indicated where there was a history of nervous breakdown, nervous insanity, suicide, mental deficiency, alcoholism, epilepsy, tuberculosis, syphilis, immorality, violent temper, crime, delinquency, or allied disorder in the patients' grand parents, parents, aunts, uncles, or siblings. In view of the fact that relatives tended to show reluctance in revealing adverse family traits it was possible that 56 per cent represented a minimum figure, a hereditary taint was found to be present in relatives of 70 per cent of mentally sound people. The difficulty of disentangling inherited and acquired factors in any particular case was such that it was not considered possible, in so varied a group of cases as this paper embraced and where figures for a control group were not available, to make positive statements regarding the part played by heredity, although in many of the cases it was undoubtedly a contributory factor.

In 562 of the cases the intelligence quotient was assessed at by the Stanford revision of the Binet-Simon scale. In the remaining 438 it was assessed on school records. Taking the series of 1,000 cases together 60 per cent were considered to be of very superior intelligence, 41.9 per cent of superior intelligence, and 29.4 per cent were dullards.

168 per cent were considered to be mentally defective. These figures differed from those expected from a sample of the ordinary population in two respects—namely in the high proportion of dullards and of mental defectives which the series contained.

In the investigation and treatment of adult cases of nervous and mental instability the history of an unhappy childhood was of frequent occurrence. It was not surprising, therefore, in investigating the nervous and mental instabilities of adolescence unhappy or unsatisfactory home circumstances were found to have contributed to a considerable extent. Nearly 45 per cent of the cases were found to have suffered parental loss as a result of which the child had lacked dual parental control or had come under the care of a step parent or other relative, or had been fostered, adopted or placed in an institution. Cases of desertion, separation or divorce were numerous. In a number of cases a parent was an inmate of a mental hospital in others the father was employed overseas. The series included seventy-seven cases of young people of illegitimate birth. Excluding this group 14 per cent of the cases were only children, in 22 per cent the patient was the eldest child, in 20.8 per cent the youngest in the family. The greatest proportion, however, actually 35.5 per cent, were found to belong to none of these groups but to the middle section of families of three or more children. There were twenty cases in which the patient was one of twins but no case in which both twins were brought for advice. Ninety-nine had been subject to court proceedings, seventy-three had been placed on probation, fifteen had been inmates of Home Office approved schools, three had been to Borstal, two had served terms of imprisonment, seven girls were the mothers of illegitimate children and thirteen of the young people had attempted suicide. After full investigation it was found that each of the cases could be placed in one of six main groups according to the diagnosis arrived at.

#### Grouping of Cases

The largest group comprising 33 per cent was made up of those cases diagnosed as conduct disorders for which no mental, physical, intellectual or purely nervous cause could be found. Cases of psychoneurosis amounted to 31 per cent, this term being used to include those conditions diagnosed or described as neurasthenia, psychasthenia, anxiety states, anxiety neurosis, anxiety hysteria, compulsion neurosis, conversion hysteria and such other conditions as stammering, enuresis and masturbation. A further 16 per cent were cases of mental deficiency and 12 per cent were found to be suffering from some organic disorder to which the symptoms complained of were attributable. Chronic epidemic encephalitis and epilepsy were the commonest of these, there being twenty-six cases of each disorder in the series. Organic lesions of the central nervous system and cases of chorea accounted for a certain number and the remainder were found to be suffering from disorders of other systems. Some 7 per cent were considered to be psychotic—that is mentally disordered, true psychotic conditions in children under 15 are of rare occurrence but become considerably more prevalent between 15 and 20, the two common varieties being dementia praecox and manic-depressive psychosis. Only 1 per cent of the cases were normal individuals seeking vocational or educational advice. Some attempt was made throughout to assess the prognosis in each case. In only 29 per cent was the prognosis considered to be favourable, while in 34 per cent it was considered to be definitely unfavourable. In the remainder it was not found easy to make a decision either way.

Treatment tended to fall into three main categories: (i) active psychological treatment which was considered in the present series of cases to be applicable in 33.3 per cent; (ii) social adjustment, or a means whereby some adjustment was brought about in the home, school, train-

ing or occupational environment which relieved the stress upon the patient and thus assisted him in overcoming his nervous or behaviour symptoms—21.6 per cent were considered to require this form of treatment; and (iii) placement which may take the form of voluntary placement in a home or training school or may require some legal measure under the various Acts relating to mental disorder, mental deficiency or unruly behaviour and was recommended in 26.8 per cent of the cases. Fall common causes of nervous and mental breakdown in young people arose out of attempts to adapt to what were for them quite unsuitable occupations. In 6.2 per cent of the series a change in occupation was the sole recommendation made, 6.4 per cent were considered to be in need of treatment along general medical lines and in the remaining 55 per cent it was not felt that a recommendation could be made.

#### Late Results

An attempt to carry out a follow-up of the cases diagnosed and treated as well as of those to which no recommendations were made was considered to be an important feature in the investigation. The matters inquired into in the follow-up were (i) general physical and physical state of the patient as compared with condition at the time of the initial examination; (ii) situation as regarded employment; and (iii) place of residence. Although an after history of one year or more had already been obtained in 52 per cent of the cases it had so far been possible to obtain a complete five year follow-up in only 12 per cent. Of the 120 cases in which the follow-up had been completed 40 per cent had made a complete recovery, 24 per cent a partial recovery, 17 per cent were unchanged and 19 per cent had deteriorated or died.

The three main sources from which the cases were derived were medical, social and official. An analysis of the findings in relation to each of these sources revealed considerable differences between the characters of the group referred by medical practitioners and those of the other two groups in which the findings showed such close similarity as to warrant their being considered together. The great majority of the first group were referred on account of nervous symptoms whereas in the other two groups the majority were referred on account of some conduct disorder. In the first group a sound family history was more commonly present than an adverse one, while in the other groups the reverse was the case. The dullard did not take a prominent place in the first group, in the other groups however dullards and mental defectives were in the majority. In the first group the normal home was three times as prevalent as the broken home, whereas in the other groups the broken home was more prevalent. The cases from medical practitioners were in the main diagnosed as suffering from a psychoneurosis and physical and mental disorders took a prominent place, cases of conduct disorder being relatively infrequent. In the other groups a large majority were cases of conduct disorder. In the first group a good or uncertain prognosis was made more frequently than an unfavourable one, while in the other two groups the reverse was the case. In the first group psychological treatment was the commonest recommendation made, while in the other groups advice as to voluntary placement was most often given, some legal measure being the next most common. Dr Hall concluded by saying that it seemed that two distinct categories of patients were being referred to psychiatrists for investigation at the present time—first persons handicapped by physical, mental or moral infirmities or who had been called into a social problem group, and secondly a group of much more promising material.

#### Other Papers

At the same meeting Dr A. G. C. FELLITT read a note on a case of trombiculosis of the face and neck. The patient was a married woman aged 9. She had had urticaria

in the right leg, since the age of 18. Thrombosis occurred in the middle third of the leg and extended proximally at the rate of two inches a day. On the seventh day a non-fatal pulmonary embolus occurred. Eventually suppression of urine and coma occurred due to obstruction of the renal veins. This persisted for three days after which the kidneys began to function again and the patient made a slow but complete recovery.

Mr JOHN ROBERTS read a paper on 120 consecutive cases of foreign body removed from the oesophagus and upper respiratory tract and in the discussion which followed Mr H V FORSTER, Dr REGINALD GEMMELL, and Dr COTTON CORNWALL took part.

## GONORRHOEA IN WOMEN AND CHILDREN

At a meeting of the London Association of the Medical Women's Federation held on March 22, with Miss E C LEWIS the president in the chair, Mrs MARGARET RORKE read a paper on this subject.

Mrs Rorke, speaking first of signs and symptoms of gonorrhoea in adults, said that diagnosis was nowadays made by films and cultures and by blood complement-fixation tests in cases with more than ten days' history of discharge. In all cases with bowel symptoms, and at some time in the treatment of cases without such symptoms, careful rectal examination and tests were required, a surprisingly large number of patients were carriers of gonococcus in the lower rectum. She spoke of the local areas most often affected—the urethra in 80 per cent of all adult women, the vulva in some, a Bartholin abscess should be treated by free incision under general anaesthesia, for otherwise a residual sinus might remain as a chronic infective focus. Cervicitis was primary and vaginitis a secondary infection; local extension might be to the bladder, causing acute cystitis, to the endometrium, and to the tubes. Extension to the peritoneum was not rare but caused remarkably few symptoms and little pyrexia after a day or two of acute pain. Warts of the vulva sometimes disappeared spontaneously if kept dry and dusted with compound "dermatol" powder or the like. They were best treated by excision under a general anaesthetic after the urethral infection had cleared up, and dressed with flavine in sterile paraffin. Trichomonas infection was often complicated by gonorrhoea, which was often not demonstrable until the trichomonas had been subdued. The possibility of gonorrhoea as an underlying focus in cases of arthritis of the wrists, hands, knees, ankles, or feet must not be forgotten.

Gonorrhoea in children was mostly due to indirect infection from towels, sheets and sanitary appliances previously used by an infected and careless adult. Direct vulvo-vaginitis due to criminal assault was relatively rare. The other direct infection was ophthalmia neonatorum, due in 90 per cent of all cases in England to the gonococcus in the mother's cervix or vagina, 100 to 120 cases were still being notified every week in England and Wales. The most modern treatment for vulvo-vaginitis was administration of an oestrin preparation (often menformon) in addition to local treatment, and prontosil album cautiously given in doses amounting to 1 or 2 grammes daily was useful in children over 18 months. Dr D K BROWN had reported good results with prontosil in a short series of cases treated at the Children's Medical Home, Widdowson. The great advantage of the treatment was the reduction of local applications to a minimum. Since a few cases of intolerance had occurred, the drug was now given for ten days only, with equally good clinical results so far; maximum total dosage 20 grammes.

Turning to treatment in adults, Mrs Rorke said that the essentials of treatment were rest, drainage of uterus, local treatment by sitz baths, douches and oral medication. The public laid far too much stress on douches,

long-continued self-administration of which often led to local damage without touching the underlying pathological condition. Rest was of paramount importance, and where treatment in bed was impracticable the patient should be urged to have long nights and Sundays in bed. Where possible, a generous diet. Local douches should be given by a trained nurse and not continued too long. When the massive purulent discharge had gone the cervix should be cleaned and dried and treated with glycerin also in combination with other drugs such as protargol or boracic on a probe. During the last few months Mrs Rorke had used prontosil album in doses of 35 to 40 grammes daily for a week and half this dose for a second week in combination with an acid or an alkaline salt depending on the vaginal pH. In the main the results were highly encouraging, and in some cases even dramatic. It was essential to watch the patient and to spread the dosage well over the day, the last tablets being taken at bed-time.

Mrs Rorke spoke of the treatment of gonorrhoea by heat, electrically or chemically produced. She had found diathermy admirable, particularly in the urethra and rectum. More recently she had procured great relief from the pain of salpingitis by the use of the E. L. machine, which consisted of a latex bag attached by rubber tubes to a small machine containing electrically heated water. The bag was placed in the vagina, and the temperature of the water was raised slowly from 110 to 128° F, the patients derived much comfort from treatment. The use of artificial pyrotherapy by Kettering hypertherm had been found beneficial in America for patients with resistant gonorrhoea. The temperature in the machine was slowly raised to 105 to 110° F, and was kept at this level for five hours. Mrs Rorke showed films demonstrating the effects of this treatment in advanced cases of gonorrhoeal arthritis. Finally she discussed tests of cure, quoting figures from the pathology laboratory at the Royal Free Hospital to show that cultures as well as films were essential. She required as minimum criteria negative films and cultures taken at the end of three menstrual periods, the last being after at least a month without treatment and after provocative painting with alcohol. The blood complement fixation test must be negative and the patient's clinical condition must be free of all signs and symptoms of infection before she was allowed to regard herself as cured.

A meeting of the Section of Pathology of the Royal Academy of Medicine in Ireland was held on April 1. Dr G C DOCKERY who presided, described a case of cirrhosis of the liver with macrocytic anaemia. Dr W R O'FARRELL showed a specimen of infarction of the ventricle. Professor J McGRATH and Dr T C O'CONNELL discussed a fatal case of carcinoma of the kidney with secondary deposits in bone, and Professor McGrath also read a paper on some methods of testing the efficiency of hospital sterilization plants. In the discussions which followed the president of the Academy, Dr A R PARSONS and Drs E HARVEY, J C HENRY, M P O'CONNOR, S J BOLAND, W A GILLESPIE and J C McSWEENEY took part.

At a meeting of the North of England Gynaecological and Obstetrical Society at Liverpool on February 25, FRANK STABLER (Leeds) described two cases of advanced extra-uterine pregnancy, Mr ST GEORGE WILSON read a case of sarcoma of the femur complicating pregnancy. Mr C J K HAMILTON (Liverpool) discussed a case of Siamese twins, Dr A A GEMMELL described a case of a sacculated pouch of the posterior wall of the bladder, and Dr C E B RICKARDS read a paper on uterine rupture following Caesarean section which will appear in the coming issue of the *British Medical Journal*.

### ENGLAND AND WALES

#### A National Physical Training College

Plans for the establishment of a national physical training college for teachers have reached an advanced stage. This was indicated by Sir Kaye Le Fleming, Chairman of Council of the B.M.A. when he gave a talk at Olympia on April 13 in the series arranged by the Association on the medical aspect of fitness. Sir Kaye, whose subject was "Physical Education in Schools," said:

I am glad to be in a position to say as a member of the National Council of Physical Fitness that the plan for this project has passed the necessary tedious process of preliminary investigation with regard to a suitable site, a process necessarily shrouded in a good deal of secrecy, and before long I am confident it will be possible to give the public more information on the subject. The college when complete will include all the necessary facilities for the purposes of training and teaching the subject such as a residential college should provide in addition to special requirements such as gymnasia, swimming baths, running tracks, a stadium and playing fields in surroundings which will be permanently secure from undesirable encroachments. Research will also be undertaken. Sir Kaye stated on such matters as the relation of physical fitness to nutrition, fatigue, heart tolerance, and muscular exertion. We have to day no standards of measurement of physical fitness. Here is a vast new field for medical and scientific research into which those who have ventured have done so as solitary explorers without any attempt at systematic and co-ordinated effort to cover the ground.

#### Health and Cleanliness Council

The Health and Cleanliness Council now a thriving twelve year old, gathered its friends together on April 13 at a luncheon in London with Dr G. F. Buchan, the president, in the chair. The large company attending included many medical officers of health, also representatives of local education departments and of voluntary organizations. The principal guests were Lord Horder and Sir Arthur MacNalty. In proposing the health of the council Lord Horder said that it stood for preventive medicine in relation to the individual and to the home. Some of its slogans—namely "Where there's dirt there's danger"—made a great appeal to him. He believed the inculcation of cleanliness struck at the very root of disease. Children took kindly to being clean if shown how and given facilities and to vary an old adage regarding the volunteers, one child who washed itself was worth ten washed children. Such work as the council undertook, Lord Horder went on, required courage and persistence, even more persistence than courage, for while there was often little difficulty about the initial effort the continued effort called for more resolution. In the home cleanliness was the preventive medicine of housing. One of the council's aims was to see that no tenant owing to lack of instruction made a contribution to new slums. In Great Britain they boasted of the best public health services in the world and not without reason, but the enemies of public health were not only poverty and economic maladjustment but ignorance and laziness and therefore such successful propaganda as the council had initiated was very much needed.

Dr G. F. Buchan said that 285 bodies, some of them municipal and some voluntary, were now represented in

the council. In preaching cleanliness as the first law of health the council had not tried to supplant any existing organization and it had worked largely through ready-made audiences of women's institutes and the like. Last year between 700 and 800 lectures were given and a very large number of posters had been displayed and pamphlets distributed. While attention was mainly directed to personal and domestic cleanliness, civic cleanliness also came within the council's ambit. Dr Buchan reminded his audience how comparatively recent a thing was cleanliness as the modern world understood it. Not until the days of Elizabeth was soap discovered and for many a long year it was a crude and expensive product. He might have added that the word "soap" does not appear in Shakespeare, though Coriolanus bids the citizens "wash their faces and keep their teeth clean." Only during the nineteenth century, said Dr Buchan, did the means of cleanliness become available for all and now there was more money spent in this country on keeping clean—including not only personal lavation but laundries, house cleansing and city scavenging—than on clothes or education. Cleanliness in fact was the index of civilization, the foundation of health, work, and of great aesthetic values.

#### Care of the Blind

Sir Kingsley Wood, the Minister of Health, after opening the new municipal workshops for the blind at Stratford, E., gave an address in the Town Hall, West Ham. He said there were some 78,000 registered blind persons in England, Wales, and Scotland, and of these nearly 50,000 were aged 50 or over. He did not think the number of blind people in this country was increasing, and owing to increased knowledge of the causes of blindness, which operated at birth and in the earlier years of life, fewer at which persons were first registered as blind were becoming progressively later. There had also been a falling tail in the number of blind children. Despite the terribleness and ineffectuality with which blindness was borne it was a terrible handicap—more particularly to the great majority of blind persons over 40 years of age—because it was not then normally practicable to train them in a new form of employment. The lowering of the pension age to 40 would at any rate secure to many of the blind population a regular source of income. He believed Parliament had also expressed the general opinion of the country in enacting that domiciliary assistance to blind people should no longer be given under the Poor Law but under the Blind Persons Act. Blind people should have as many contacts as possible with life and the world. It did much for their adaptability that many of them were filling odd jobs, positions not only of responsibility but such as required considerable technical and mechanical skill and aptitude. The blind had contributed many able members to professions and many skilful craftsmen to trade and industry. Prevention of infantile blindness and preservation of the sight of school children were having an increasing effect in restricting the number of persons becoming blind in early life. The Minister in conclusion stressed the importance of home visiting and home teaching. Efficient visiting helped to discover cases of blindness and he particularly desired to see the blind trained in the early years of their affliction.

#### Milk Pasteurization Plant

In view of the increasing number of pasteurizing plants the Royal Sanitary Institute (90 Buckingham Palace Road, S.W. 1) conducted during the winter of 1937-38 a series of lectures and demonstrations for medical officers of health, sanitary inspectors, and others interested in the subject of pasteurization. During the course of these arrangements were made for those at end of the road to visit the plant in operation which proved very helpful to illustrate the difficulties to be overcome in practice. It seemed

evident that the demand for such courses was not fully met so it has been decided to hold a further course on Thursday and Friday May 26 and 27

### Research in Surgery at Edinburgh

A unit for clinical research in surgery has been established at Edinburgh by the Medical Research Council, acting jointly with the Royal Infirmary, the University, and the Royal Hospital for Sick Children. The unit will be located in the Infirmary, with facilities also in the University Department of Surgery and at the hospital. The director is Mr W C Wilson FRCS Ed, who has for this purpose been appointed to the whole-time staff of the Council. The arrangement has at present been made for a period of five years from April 1, 1938. The establishment of "units" or departments of this kind in selected hospitals forms part of a policy adopted by the Medical Research Council for the promotion of research work in clinical science, as opposed to the laboratory branches of medicine. Two units for research in clinical medicine and one for research in neurology have already been established in London. The new surgical unit is the first one under the scheme to be set up outside the Metropolis.

### Mental Defectives as Good Citizens

In an address to the Edinburgh Committee for Mental Welfare on April 4 Dr W M C Harrowes, physician to New Saughtonhall Mental Hospital, said there was no more useful citizen than the mentally defective person if he received good habit training. Society would always need hewers of wood and drawers of water, and if the mental defective was properly habit-trained he would be content with these menial occupations and, indeed, was far better at them than anyone else. Parental authority was seldom questioned by society except in flagrant instances, but it was always being questioned by the child, sometimes aggressively sometimes implicitly, but always with reason. A certain quality, which William James had called sagacity and which was customarily called judgment or common sense existed as an innate endowment, and the child's capacity for judgment was similar to that of the adult. The child's life was simple with few distractions and he was the closest possible scrutineer of discrepancies in conduct. The adult before criticizing the child should examine his own attitude to authority. Much was heard to-day of the controversy about the relative influence of environment and heredity in causing maladjustment, but the facts of each case should be taken for what they were worth. The important principles in any investigation of a case of maladjustment in child or adult were freedom from preconception and readiness to utilize proved facts dealing with the individual as a unit in changing environment and refusal to use a complicated technical terminology. The chairman, Mr Charles Milne KC said that the need for a remand home for juvenile delinquency in Edinburgh was urgent, and the plans for a new home were already in preparation. Many cases of juvenile delinquency were really cases of mental deficiency.

### "Fitter Britain" at Glasgow

The Empire Exhibition at Glasgow, which is to be opened by the King on May 3 will include in the United Kingdom Government Pavilion—a building equal in area to St Paul's Cathedral—a "Fitter Britain" exhibit, arranged by the Ministry of Health in collaboration with the Board of Education, the Scottish Department of Health and the National Fitness Council. The exhibit, the most ambitious scheme of the kind the Ministry has ever attempted is in portable form and when the exhibition at Glasgow is over it will be shown in other parts

of the country, and may be seen in London early next year. The most startling feature is a piece of mechanical engineering in the form of a working model four times life-size, of the upper part of the human body showing the processes of respiration and digestion and the circulation of the blood. Thanks to the modern technique of sound-recording, the "mechanical man" will lecture on his own physiology every quarter of an hour. More artistic if less fascinating will be a gigantic sculpture representing the ideal man, woman, and child after which the National Fitness Council strives, and below this will be a panel of facts and statistics illustrating the improvements in national health during the last century and especially the last forty years. A model of a central health clinic is one of the leading features of the exhibit and reproduces on a small scale the apparatus for orthopaedic and x-ray treatment, the arrangements for maternity and child welfare, and so forth, all in minute detail down to the liquid soap containers and the accessories of the dental chair. A model of a general hospital has been lent by the King Edward's Hospital Fund, and here again everything is in scale, down to the bedspreads which replace handkerchiefs given by ladies of the Royal Family. In the bays on either side of the hall there have been arranged illuminated pictorial sets depicting the modern care of infants (contrasting the methods of Betty Hilder in *Our Mutual Friend* with infant hygiene as practised to-day), the work of the school medical service, the provision of games and recreation in a community centre, the work on nutrition and on housing, and the guard against infectious disease. The story of some of the enemies of health—tuberculosis, cancer, venereal disease, rheumatism—will be graphically told, and the agency of the bed-bug, the flea, the house-fly and the louse in spreading disease will be vividly brought home.

The Ministry of Health exhibit will not be the only one that deals with health. The work of the R.A.M.C. is to be shown in the Army Pavilion, and the Home Office has an exhibit illustrating methods of accident avoidance in factories. Here power presses, hydro-extractors, circular saws, printing machines, and machines used in the food trades will be shown with which it is almost impossible to sustain an injury. One machine is so interlocked that the operative cannot put his hand into the danger zone, in another, if he does place his hand near the danger zone, the machine stops instantly, in yet another, if the hand is brought near the rolls of the machine they will reverse and push the hand out of danger instead of drawing it in. Other Home Office exhibits deal with ventilation, lighting, protective clothing and first-aid equipment. Scotland itself is represented by two pavilions, one showing its past and the other its present, and in the latter there is being staged the statutory services which are provided for the individual from before birth down to old age. The contribution of Scotland to medicine is the subject of an exhibit in which the Scottish Committee of the British Medical Association has collaborated with the Department of Health, it is far historical in character, and deals with the part played by individuals, medical schools, and hospitals.

At a Government reception to the Press the other day those who attended were given an embarrassing amount of typewritten material testifying to the research and ingenuity of those responsible for the department's exhibits. But in those which had to do with health and fitness no reference was made to private practice, and one might have imagined the family doctor to be non-existent. The first bulwark of the State will be represented among other mural paintings in the vestibule. It is natural that in an exhibit arranged by the Government statutory health services should be emphasized, but the medical service under the National Health Insurance Acts is a statutory service and no reference whatever is made of it in the 16 page pamphlet *Fitter Britain Exhibit* issued with the compliments of the Ministry of Health.

## Correspondence

### After-effects of Modern Treatment of Carcinoma

SIR—The correspondence following my original communication (*Journal* February 26 p 430) has been interesting and instructive. From it I realize that there is no generally accepted method of applying radium; that selection of the best method of treatment for each individual case depends purely on the surgeon's predilection; that the miseries of radium necrosis, neuritis and myalgia are still of frequent occurrence; and that no correspondent of mine has ever been warned of the possibility of this before treatment began. Walkhoff and Giesel announced in 1900 that radium had certain physiological effects and Professor Regaud wrote in 1934: "Madame Curie can be counted among the eventual victims of the radioactive bodies." Surely these facts call for further research; the results of which should be readily available to all members of the profession—I am, etc.

### Classification of Adventitious Sounds

SIR—A most important point is raised by the correspondence on the classification of adventitious sounds. While it is interesting to follow the development of the nomenclature from the time of Laennec onwards it is unfortunately of very little use to the student of to-day who is often confused by the different terms which are used by his teachers to describe the same sign. The ideal classification should have the merit of brevity and conciseness and should avoid so far as possible the use of indeterminate adjectives; it is also desirable that the recognition of an added sound should help to indicate the site and probable nature of the condition which causes it. The following classification seems to me to meet the requirements of the student:

1 *Sounds produced by Narrowing of the Bronchial Tubes*—These are sometimes termed "continuous sounds"—rhonchus and sibilus. The rhonchus is low in pitch and is produced in the larger bronchial tubes; the sibilus high pitched is produced in the bronchioles. Each of these sounds indicates narrowing of the tube by swelling or by spasm and they are therefore present in bronchitis and in asthma.

2 *Rales*—These are bubbling noises which are produced by the passage of air through liquid. They may be heard when the liquid is in a bronchial tube or in a cavity in the lung tissue. They are therefore a feature of pulmonary congestion, bronchiectasis, certain types of lung abscess and of tuberculo with cavitation. They may also be heard in other conditions which produce the necessary combination of air passing through liquid.

3 *Creptations*—These are the finest of all added sounds and are produced by abrupt separation of the walls of the alveoli. Creptations therefore indicate a lesion of the lung parenchyma and they are most commonly heard in early and late pneumonia and in early pulmonary tuberculo.

The adoption of a classification of this type would greatly simplify the problem, which confronts the student and it has the additional advantage that a fairly clear mental picture is conveyed of the type or process which is causing the adventitious sound—I am, etc.

London W 1 April 14

JAMES MAXWELL

### Modern Views on Pellagra

SIR—Drs W J Dann and Y Subbarov in a letter in the *Journal* of April 9 (p 809) make the statement that "applying these criteria, canine black tongue and the recently described disease in pigs (Chick H *et al* 1935 *Br J Vet J* 32 10) are the only true analogues of human pellagra which we know to-day." From the description given of the condition in pigs it seems almost certain that we are dealing here with one of the major sequelae of iron deficiency. In connexion with this condition I have noted elsewhere that in a certain proportion of the affected pigs there occurred as a late manifestation an anaemia of the macrocytic type which was associated with great distention of the parenchyma of the liver. This anaemia was completely refractory to treatment with iron but responded to feeding with raw liver. I interpreted these findings as indicating (1) that in the normal animal iron is elaborated further a precursor substance formed in the stomach by the interaction of intrinsic and extrinsic factors; and (2) that in such cases as have at present yielded to feeding with raw liver, as demonstrated chiefly because of the great distention of the liver, the condition which however acted in combination with a toxic deranged by the anaemia (with consequent effect on the intrinsic factor) and told of a nature affording a poor supply of extrinsic factor. Absorption did not appear to be affected as was evidenced by the reaction to liver extract administered orally.

In 1931 in collaboration with Dr R D Sinclair (*Edin Med J* 1931 38 403) I showed that the anaemia (and the condition as a whole) could be influenced in a rather dramatic fashion by the oral administration of a liver extract. Recently Elvehjem has demonstrated that liver extract has as one of its important ingredients nicotinic amide. Under these circumstances two points of considerable moment arise for consideration. In the first place it seems possible that yeast may contain preformed as a nicotinic acid containing body, liver agent precursor—that is to say the equivalent of the interaction of intrinsic and extrinsic factors; and secondly the question arises as to whether we are really dealing here with a condition comparable to pellagra as it occurs in human beings. It thus happens to be the case, unfortunately, that will have been thrown on the details of the general human disease—I am, etc.

Aberdeen April 11

J P McGOVERN

### Pasteurization of Milk

SIR—I must admit to Dr Halliday Sutherland (*Journal* April 9 p 812) that I gave out slight attention to his suggestion that the substitution of pasteurized for raw milk might prejudice human fertility. As he cited no evidence in support of this proposition and as in a fairly varied dietetic and climatic conditions man has not failed to multiply and to replenish the earth, a speculative possibility of the effect of a slight vitamin change in a relatively small factor of an ordinary mixed diet seemed to me to offer no chance of fruitful discussion. Even if ineffective would be the consideration of the possibility of confining man to a diet consisting solely of pasteurized milk for no one proposes this as a mere experiment. Even if it be true that the use of pasteurized milk and the falling birth rate have an apparent time relation Dr Sutherland is hardly of those who argue that the burning of Tenterden sheep is responsible for the condensed appearance of the Galloway Sires.

Since writing my letter (April 2, p 753) I have learned that an experiment much on the lines desired by Dr Sutherland has already been made and recorded. Conducted under strictly scientific conditions of observation and control, the experiment in essence was a study of the effects of raw and pasteurized milk, respectively, in two groups of mice, each comprising some 1,100 individuals. Among the conclusions supported by full statistical details may be read "Little or no difference was noticeable between the raw and pasteurized groups in relation to rapidity of conception, average number of litters produced, or average number of litters reared" (G S Wilson and Irene Maier, *Journal of Dairy Research* June, 1937). Professor Wilson's study is valuable in several directions, but I must limit my quotation to the point on which Dr Sutherland particularly desires information—I am, etc,

London W1 April 12

C O HAWTHORNE

SIR—Although I am not a member of the medical profession I have been a producer of tuberculin-tested milk for a good many years, and have always taken the closest interest in the Raw v Pasteurized Milk controversy. It seems to me that in many cases misleading conclusions have been drawn from experiments which have been carried out. In Professor G S Wilson's experiment, for instance, which has been much quoted, although it was stated that there was no difference in outward appearance between calves fed on raw and those on pasteurized milk, I would call attention to the fact that there was a considerable difference in the prices realized, even excluding those calves which were admitted to have suffered from scour in the pasteurized group. This difference cannot be easily explained away.

In the later Hannah experiment, which has also received much publicity, the results of the inspection by four separate judges—who classified the calves into three different classes (A) those in exceptionally good condition, (B) those in a satisfactory condition, and (C) those in a definitely unthrifty condition—show the following: Calf No 9 was classified by one judge in Class A, by two judges in Class B, and by one judge in Class C; Calf No 11 by two judges in Class A, one in Class B, and one in Class C; Calf No 13 by one judge in Class A, one in Class B, two in Class C; Calf No 17 by one judge in Class A, two in Class B, one in Class C; Calf No 25 by one judge in Class A, by two in Class B, and one in Class C. These are not the only examples, but others could be chosen, showing that there was great diversity of opinion. Calf No 36, for instance, was classed by three judges in Class A and by one judge in Class C. How is it possible to reconcile judges' conclusions such as these? Surely, although there may be some doubt about classification, there should be no doubt whatsoever as between "exceptionally good condition" and "definitely unthrifty," and yet these are the results on which we are asked to compel the public to buy pasteurized milk.

I should like to see experiments carried out to decide the relative growth in raw and pasteurized milk of pathogenic bacteria which have passed successfully through the process. Surely Dr James Kirkland will not maintain that all thermotolerant strains of *B coli* are non-pathogenic. If so on what evidence does he base his conclusions?

Would it not be better if the British Medical Association were to pay some attention to the grossly excessive margins demanded by the large dairy companies in London for tuberculin-tested milk so that this could find its way into more homes and more producers be induced to set their house in order? Perhaps they are unaware that ordinary

milk pasteurized costs 3½d per pint tuberculin tested and a pasteurized 4½d, or 8d per gallon more, whereas tuberculin-tested milk unpasteurized is priced at 8d per pint—a wholly ridiculous price, and unjustifiable under any conditions, except for the desire to prohibit the public from purchasing the best that a farmer can produce. It will not maintain for one moment that all milk produced on the ordinary farm is satisfactory—far from it—but surely the aim should be to find a market for the best and to encourage its production by giving the producer a fair deal, while allowing those who are convinced that pasteurization does have some effect in the long run to purchase the class of milk which they are willing and anxious to use—I am, etc,

Rowallan, Kilmarnock, April 12

ROWALLAN

SIR,—Dr Lionel J Picton refers to my letter in the *Journal* of March 26 (p 704) as "a refreshing breeze in the stale atmosphere of the milk spoliators." May I return the compliment by saying that his letter (April 9, p 817) reminded me of the meeting of Stanley and Livingston in Darkest Africa. I am also grateful for his reference to the work of E C V Mattick and J Golding, which I had missed. Nevertheless, the experiment he quotes refers to sterilized milk which had been held for an hour at a temperature of 210° to 212° F. Our opponents may point out that pasteurized milk is held at a temperature between 145° and 150° F for half an hour. A third experiment of Mattick and Golding (*Lancet* 1931, 1, 666) shows the effect of pasteurized as distinct from sterilized milk on the fertility of rats.

Eighteen buck rats were divided into three groups of six. In addition to a diet common to all, group A had whole raw milk, Group B had pasteurized milk, and Group C had sterilized milk. Eighteen does were likewise divided into three groups and fed like the bucks. On reaching maturity the rats in the corresponding groups were cross-mated on the same day. None of the does in Group C became pregnant. All does fed either on raw milk or on pasteurized milk did become pregnant. The raw milk group produced forty-seven offspring, of which forty-one were born alive; the pasteurized milk group produced forty-two, of which only twenty-two were born alive. Its fertility be the capacity to produce healthy offspring then on this experiment, pasteurization reduced fertility by over 52 per cent. It may well be that none of the known vitamins is so exclusively specific in its action as is generally supposed, that in whole raw milk there is a vitamin balance, and that the upsetting of this balance by pasteurization has an adverse effect on fertility. More experiments are urgently needed, and with depopulation in the offing the rats which Dr Picton pities may help to save a sinking ship—I am, etc,

London, W8 April 11

HALLIDAY SUTHERLAND

### Posture and Painful Feet

SIR,—The reading of the report of the discussion on "Painful Feet" in the *Journal* of April 2 (p 748) leaves one with feelings of despair for those who are suffering, and all those who will be allowed to suffer from this painful condition if their only hope of relief is in the ministrations of the chiropodist with his pads or in operations by the orthopaedic surgeon. Neither can produce a feeling of hope of ever understanding the cause or its prevention and cure, to talk about 'evolution or regression' or to "blame the shoemaker" does not give us the kind of shoes we desire to have.

In every case of 'painful feet' it will be found that the patient's posture is bad as the result of physical

and functioning of the whole body including the feet—the pain in the feet being the most obvious result to the patient but by no means the only one. In the discussion no speaker mentioned this constantly acting cause and naturally no reference was made to how it was to be removed. That the condition can be relieved by many different procedures is well known but so long as patients have to wear supports and other adventitious aids they cannot be said to be cured while they are still left with their bad use and bad posture against which the whole body as well as their poor feet are struggling, whereas when the only treatment given is a general (not specific) re-education in the use of the self, for the correction of the postural defects not only does the patient recover from his painful feet but he experiences a great physical as well as mental sense of well-being. The cases may differ widely in the character and degree of the bad use and malfunctioning and the resulting postural defects but the method of re-education is the same because the primary cause is the same.

To the profession this theory of bad use with bad functioning leading to postural defects is new so that the idea of correcting postural defects with their accompanying disabilities whatever they are by re-educating the patient in a better use of himself is also new not to say revolutionary. But the results in the sphere of prevention are only equalled by its practical results in the sphere of alleviation when defects and disabilities have arisen.

To explain the theory and give the anatomical and physiological data on which it rests would be beyond the scope of this letter. Let it suffice to say that the key-note of all use and functioning lies in the relative position of the head to the spine at the atlanto occipital joint and our capacity to use and direct it in a direction which can best be described as forward and upward instead of backward and downward as it is found to be in every case of bad use and functioning with accompanying postural defects such as will be found to exist in every case of painful feet—I am, etc.

### Facial Wounds

SIR—With regard to the method of adapting the thin edge of the apex of the upper flap of an oblique cut Mr Julian Taylor in his article on facial wounds (*Journal* April 9, p. 792) advocates a practice which has stood the test of time. When the oblique cut has penetrated the deep tissues difficulty arises and the under flap which has a tendency to curl in needs anchoring. This I effect by means of a removable continuous silkworm gut suture. Poin's in wound healing which most writers do not sufficiently deal with are the questions of time and support. I doubt whether facial cuts are any better treated to day than they were in the past. I am quite certain that the simpler the measures employed the better for all concerned. All endeavours to elaborate a quite unnecessary plastic technique should be discouraged.

The majority of surgeons recommend that their surface stitches be removed in three days. They say that three days is sufficient for union and after any longer period suture marks remain. Here I disagree. Because the epidermis is in contact it does not follow that the sub-strata are in contact. That scar tissue forms eventually—as a thin white line which may be raised level or sunken—can only be accounted for by the fact that the deeper tissues unsupported have retracted and the space has been filled with granulation and later scar tissue. General practitioners who employ plaster in either narrow

strips or broad bands to adjust facial cuts often produce results surpassing the most expensive efforts of the plastic specialists. Strapping is the alternative to suturing and if the answers very well there is a modification of the method which may appeal to man.

For facial cuts I suggest the use of that cheap and transparent cellulose product which encloses the cellulose fast kipper and can be sterilized by boiling. I may be obtained in large sheets and with a suitable plaster and adhesive plaster at each end the wound can be drawn together the accuracy of the contact being visible all the time. If preferred a trace of vaseline can be applied to the surface apposed to the wound.

In discussing the suture of muscle and deeper tissue Mr Taylor refers to unnecessary buried sutures in a field of doubtful cleanliness. I do not bury sutures in these cases because the degree of cleanliness is often an unknown quantity and a frequent cause of trouble. My own procedure is to employ a long continuous suture of fine silkworm gut suture leaving the ends protruding so that they can be withdrawn in ten days time. I pierce the flesh with a household needle through which the silkworm gut can be threaded rather than triangular pointed needles the round needle pushes aside—all others cut.

A last point is whether the skin wound heals better under a scab or moist surface. The wound does not produce a scab as a protection but merely because it cannot evacuate its discharge. A moist or oiled surface allows for this—I am, etc.

London April 12

J. L. A. MARD

### Whooping-cough Treated by Ether

SIR—Fifteen years ago I had to treat a severe case of whooping-cough and after a preliminary failure with the usual measures I gave the child daily injections of ether with remarkable results. I may add that the patient though the remedy worse than the disease. My brother Dr Edward Milton treated several of his patients on the same lines with equally good results but unfortunately had two mishaps with broken hypodermic needles one of which had to be removed by operation. In spite of this the mother of that particular child begged him for the treatment as it was so markedly beneficial. In two accidents led me to experiment with ether generally and the results have been so good that I have never used any other form of treatment. My brother tells me that in the case of babies whooping-cough can be easily controlled he still gives daily intramuscular injections of 5 minims of ether and that so infrequently a weeks treatment practically cures the condition.

With ether given orally I find that in the great majority of cases provided there are no complications such as bronchitis or bronchopneumonia present when beginning treatment the disease is subdued in three weeks. For a day or two there may not be any marked change in whooping cough has a certain momentum which can be immediately checked but the attack may return so rapid and continuous the paroxysms becoming less in frequency and severity until the cough altogether. In most cases I find an entire absence of physical deterioration appetite and bodily vigour return almost immediately. Occasionally I notice that the cough is more or less bubbly during the treatment but I do regard this as it never causes distress and does no harm. In two of my cases I found the earliest successful treatment of children already had diffuse bronchitis and were running

capped by insufficient food, warmth, etc., owing to the fact that their father was out of work. I had to send them into hospital, and I believe that one of them died.

Ether is unpleasant, but children will take it readily if it is dispensed with a pleasant vehicle. I usually employ a preparation called 'Mist tam co rub infans,' and also add tincture of quillara as I think it helps to emulsify the ether and delay its separation. The dose of ether is from 2 to 4 minims and I order it to be given every two hours. In my public assistance work I have had to use a vehicle that any and every chemist stocks, and I have found that syrup simplex gives equally good results and children take it willingly. In the case of very young children I keep to the smaller dose, but in others I increase it slowly to 4 minims. I warn parents to keep the mixture in a cool spot, the bottle tightly corked, and to avoid proximity to a naked light or radiator when pouring out a dose.

I commend this treatment as being effective, inexpensive, and pleasant. The ingredients are to hand in every dispensary and the prescription in its simplest form consists of ether 2 minims, tincture of quillara, 1 minim, syrup simplex, 30 minims, with water to 60 minims. This represents a single dose, to be taken every two hours—1 i.m. etc.,

Iltham SE 9 April 7

WILLIAM T. MILTON

### Pneumonitis

SIR—Considering the present evidence, surely it would be better to regard the cases of 'pneumonitis' as atypical forms of pneumonia. What is lobar pneumonia but a form of 'pneumonitis'? Until one of these patients dies and furnishes a specific pathological picture the term 'pneumonitis' will remain a vague theoretical designation of very little value. Dr C. Hardwick (*Journal*, April 9 p. 815) says, "It is surely time we ceased classifying under the term 'pneumonia' illnesses differing widely in their course and final outcome." First, the cases described are not so widely different from pneumonia, secondly every physician has seen cases differing widely in

course and final outcome' which were undoubtedly cases of pneumonia. It is the underlying pathology which is of importance in such a classification. An apparent pneumonic reaction has been observed near an area of bronchiectasis. In a short paragraph Dr A. Morton Gill (March 5 p. 504) describes this condition as a secondary form of 'pneumonitis'. However, he appears to have omitted a lipiodol examination in any of his primary cases and has thus failed to exclude a bronchiectatic factor in these cases. The term 'pneumonitis,' as used in the current literature appears to be an unnecessary and misleading addition to the already cumbersome vocabulary of medicine—I am, etc.,

R. B. HEISCH

### Fracture of the Neck of the Femur

SIR—Mr T. P. McMurray (*Journal* February 12, p. 330) states that the success of his operation of oblique osteotomy is due to the use of the same principle as is employed in the Whitman and Smith-Petersen manoeuvres—namely the forcing of the two fractured surfaces closely together. I would suggest that if figure 2 in his article is not merely a diagram but represents the actual state of affairs there may be another explanation. This figure shows the ends thrown out from the surface of the lower fragment of the shaft to be actually merging with the callus between the fractured ends of the neck. May not

the explanation of union be that the fracture of the neck has been stimulated to callus formation by the pressure in its immediate neighbourhood of an area of new bone formation, or even that osteoblasts from this area have actually penetrated between the fragments? If this explanation were true it would mean that the upper surface of the lower fragment was acting as a bone graft, and as a bone graft with the unique property of being able to supply the callus required.

Bone grafting in the treatment of fractures of the neck of the femur has been widely practised, but apparently it has not been successful enough and so has not become a standard operation. The great fault of solid bone grafts for fractures is that it is too much to expect that the fractured bone should deal with a huge graft when it has already shown that it is unable to unite itself. The fact that grafts often unite, however, would seem to point to the fact that the fresh bone has a stimulating effect. With the idea of increasing this stimulating effect and of making the graft a less inert piece of bone, I recently suggested in a letter to the *Medical Journal of Australia* (November 27, 1937) that the graft should be cut but not completely separated from its host. After an interval during which it was hoped that the graft would be colonized with bone-forming cells—and which was roughly guessed to be between ten and fourteen days—the graft was to be shifted. This suggestion might apply to solid bone grafts for the neck of the femur. Bone grafting of the neck of the femur, however, is not easy, and if this principle is to be applied some simpler method would have to be used. In the letter already referred to I suggested in regard to fractures of the neck of the femur that the following procedure be carried out:

A trapdoor is made in the subcutaneous wall of the thigh. The spongy bone beneath is gently broken and left in situ. After a suitable interval for colonizing a wide bore needle is passed down so that its point lies between two fragments of the neck of the femur and its position is checked radiologically. The trap is again lifted and with a powerful syringe the bone beneath is sucked up and then injected through the needle into the space between the femoral fragments. It was also suggested that this technique could be applied to multiple subcutaneous drilling (Buck).

Since writing this letter an article by Mr Thomas King of Melbourne has changed my ideas as to the technique of grafting in these cases. The article is on 'The red spongiosa bone transplant for ununited fractures' (*Medical Journal of Australia* March 19, 1938). The important point presented is that the bone for grafting is taken from the red spongiosa of the great trochanter. It is sawed out and when in position is gently hammered to make a packing paste. King, as a result of his study of McMurray's experiments and of his own cases, is convinced not only that the greater part of the transplant lives but that it contains some unknown osteogenic stimulating substance. He reports seven successful cases, in two of which previous bone grafting by ordinary methods had failed. I now think that the material for grafting should be taken from the red spongiosa of the great trochanter. Mr King considers that the fresh spongiosa contains an abundance of bone-stimulating material, it would hardly be logical to transplant fresh material to an area already containing a quantity of spongiosa. I think it is anything in this suggestion, that the bone grafted already contains a quantity of bone-forming cells. It is to be remembered that it must survive in a relatively avascular area and for this reason I think it is necessary, after cutting the trap in the thigh, to break up the underlying bone and then to

for an interval during which it will be colonized by osteoblasts. At the height of this regenerative activity but before callus has formed it is transplanted to its new area, where it is hoped it will not only continue to grow and rapidly form callus but it will stimulate the broken surfaces to a similar activity.

With regard to the technique of transferring the spongiosa the needle could be put straight down through the soft tissues into the fractured interval with the leg in outward rotation or else a hole could be bored up through the trochanter and neck to the fracture site and the needle inserted through this. Before insertion the spongiosa would probably have to be gently hammered into a pistil and the syringe would probably have to be constructed on the principle of a grease gun. After gritting the leg would have to be supported by a plaster cast as described by Mr McMurray or in the case of old and feeble patients by a Hamilton Russell apparatus—I am etc

MD MS FRACS

### Chronic Litritis

SIR,—In my paper on chronic litritis (*Journal* February 26 p 448) I wished to stress the part played by the hand syringe in the production of this condition. It would be a matter for regret, therefore if Dr Sydney M Laird's difference with me as to the mechanism of this result (March 12 p 594 and April 9 p 516) should obscure our agreement as to the causal relation of the hand syringe. With all respect for the great authority of Georges Luys I am not convinced by the quotations given in Dr Laird's letter the fact that irrigations and instillations are not effective in the treatment of chronic litritis does not prove that they do not penetrate into the glands—there is the alternative possibility that even having done so they are not effective. The argument that diuresis must lead to increased intra uterine pressure is not self evident and having regard to the physiology of micturition I doubt if any marked rise in pressure does occur. Dr Laird's experimental test of the relative pressures produced by the hand syringe and the douche apparatus is striking, but I am not sufficiently versed in physics to be able to reconcile it with the principle of the hydraulic press. The grease gun used in lubricating motor cars is a hand syringe and it certainly produces very high pressures. Does Dr Laird think a douche would be as effective for removing curcum from the ear or producing infiltration anaesthesia as a hand syringe?—I am, etc,

Salford April 10 R C WEBSTER

### The Dosage of Tuberculin

SIR—It is my duty to call attention to a mistake regarding the dosage of tuberculin in the 1920 edition of *The Principles and Practice of Medicine* by Sir William Osler and Dr Thomas McCrae (p 160) repeated (as I discovered only yesterday) in the eleventh edition (1930). These are the words in the edition of 1930 (p 162)

If into a healthy person 0.25 cc of original tuberculin injected there is a slight fever with a feeling of uneasiness which passes off in from twelve to twenty four hours. It is in individual with a focus of tuberculo is dose of 0.25 cc of tuberculin are injected subcutaneously there is a reactive focal reaction about the tuberculous lesion and a constitutional reaction (fever general pains etc). This process known as the tuberculin reaction is not often used now for diagnosis.

In the twelfth edition (1935) this passage is substantially the same but it ends. This tuberculin reaction is not used now for diagnosis.

In my own experience dated from 1891 I have used tuberculin for diagnosis and since 1892 I have consistently given doses not of 0.015 cc m T A or T A F but one fiftieth part of this amount increasing the diagnostic dose cautiously and never going beyond 0.01 cc m T A or T A F. At my Tuberculin Clinic we are using these test doses in doubtful cases of tuberculosis in hundreds of cases every year with eminent success and no semblance of danger. But if we employed the diagnostic doses given in Osler and McCrae's textbook we should soon have to close our clinic. The proper use of tuberculin in diagnosis can be learnt in a few weeks but the use of tuberculin in treatment needs the experience of many years. The need for experience and great caution in the therapeutic use of tuberculin is emphasized in the 1930 and 1935 editions of Osler and McCrae—I am etc

### Blue Eyes in Natives of Ceylon

SIR—When in Kandy Ceylon recently I happened across a guide to the temple who had deep blue eyes combined with full dark skin colour and jet black wavy hair. This gave him such a peculiar appearance that I asked about his blue eyes. There was no indication of racial crossing in his features and he maintained that he was of pure Singhalese descent Kandyan caste. Several of his ancestors and relatives had shown the same blue eyes combined with the usual dark colour of the skin. His son had blue eyes also his mother and her mother as well as one of his sisters all his other relatives having brown eyes. Careful questioning elicited the facts which are shown in the following pedigree where  $\square$  = blue and  $\square$  = brown eyes.

Unfortunately as his family lived some distance away I was unable to examine any of them. His own eyes were a clear dark blue without any visible brown pigment. This pedigree suggests a dominant blue which may have arisen as an independent mutation in Ceylon. My informant stated that he knows cases of blue eyes in two other families unrelated to his own. This interpretation seems the most likely because if the blue is recessive brown eyed consorts in each of the three generations must have been heterozygous for blue. That is not impossible but it would imply that heterozygotes resemble the blue eyed widespread in the population. Blue eyes are evidently a real rarity the vast majority of the population having brown eyes. From observation of the colour in Kandy it was found that most of the people had a dark brown (black) intense colour but a few had a paler medium brown eyes. I may be that the blue eyes are due to an intensifying factor which is absent from the brown eyes.

The fact that blue eyes occur in a population with black skin indicates that the factor for blue eye-colour is a mutation independent of the factors for skin-colour although the two loci may be genetically linked. In a study of crosses between Ojibway Indians and Europeans in Northern Canada,<sup>1</sup> certain individuals of mixed descent were found to have medium skin colour and blue eyes with only a little brown pigment. From these and other observations it was concluded that in these crosses certain factors for eye colour were either independent of certain factors for skin colour or genetically linked with them. From the present case in Ceylon, it may be concluded that a mutation affecting eye colour alone has probably arisen in a race having dark skin-colour—I am, etc.,

R. RUGGLES GATES

### Multiplicity of Special Diplomas

SIR—Dr F. Hernaman-Johnson seems to be a little inconsistent when in the *Journal* of April 9 (p. 814) he expresses his agreement with "H. M. S." general thesis (March 26 p. 704) and then takes such pains to prove the desirability of having two examinations in radiology, one for the diploma and the other for the fellowship. Moreover he appears to be in error when he states that the diploma may be taken within a year of graduation, as the regulations I think, say that no registered medical practitioner may enter for the diploma course unless he has been qualified at least two years. Admittedly the present diploma is of little value but whose fault is this? The blame must be laid at the door of those who are now awarding themselves foundation fellowships. It is they who have already held the highest offices in the gift of their radiological colleagues who are responsible for the low standard of the diploma examination, and all they propose to do now is to create another examination. The reasons given for doing this are puerile. What would one think of the Royal College of Surgeons if they held two examinations of differing standards for their fellowship—one for the "rabbits," who are doomed to practise in the smaller centres throughout the country and another for the "tigers," who will be privileged to practise in London or the large provincial towns? Surely the solution is perfectly simple. All that need be done is either to abolish the diploma and retain the fellowship or to raise the standard of the diploma to that of the fellowship and then drop the fellowship. There certainly is no advantage in retaining both examinations. I know that many are in agreement with this view—I am, etc.

London W.1 April 11

F. G. NICHOLAS

### Blood Sedimentation Rate

SIR—In the *Journal* of April 2 (p. 722) I read with great interest Dr E. Scott's paper on the rate of sedimentation of red blood cells as a clinical test in general practice. I have used Linzenmeier's method of estimating the blood sedimentation rate in the diagnosis and prognosis of several diseases. The test was employed in cases of phlebitis complicating varicose veins or pregnancy. The rate was found to be raised in cases of septic origin and normal in simple thrombotic cases. This finding conformed to R. F. Payne's classification (*Journal* May 2 1937 p. 577). He considers that there are two main types of phlebitis in varicose veins: (1) a septic bacterial

phlebitis characterized by a rapidly spreading septic thrombosis, and (2) a purely thrombotic process of non-bacterial origin, secondary to changes in the damaged endothelium. Cases of phlebitis coming within an intermediate group are common in general practice. In such cases particularly I found the estimation of the blood sedimentation rate helpful. If the rate was normal an elastoplast bandage was applied to the limb and the patient allowed to walk about. If the rate was accelerated a bandage was also applied to the limb, but the patient was kept in bed until the sedimentation rate was at or near normal. One woman, who refused to remain in bed in spite of a comparatively high rate, developed pulmonary infarction due to an embolus, and died. The test was used before beginning injection treatment of varicose veins in order to exclude the presence of sepsis, particularly where there was a history of recent phlebitis.

In pernicious anaemia the diminution in the number of red cells causes an increase in the blood sedimentation rate which returns to within normal limits as the blood condition improves with treatment. Reichel (1935, *Klin. Woch.* 14, 1679) considers decrease of the rate more important in the diagnosis of a remission than the reticulocyte crisis, for the latter may be overlooked unless numerous counts are made, and occasionally a crisis may occur without being followed by a remission. The following data are from one of my cases of pernicious anaemia.

Erythrocytes	Hæmoglobin	Colour Index	Blood Sedimentation Rate
1,400,000	40%	1.4	22 mm
3,210,000	65%	1.0	15 mm
4,820,000	90%	0.9	4 mm

The test was found to be helpful in the diagnosis of articular and cardiac rheumatism, and, in my opinion, was more sensitive in assessing the degree of infection than were the temperature and pulse rate. The blood sedimentation rate was accelerated in all active cases and returned to normal after the acute or subacute symptoms had subsided. Thirty-six cases of fibrositis and sciatica were examined and each gave a normal rate. This finding is important in that it assists one to differentiate true rheumatic infection, possibly manifested only by a mild febrile disorder or by 'growing pains' in children, from inflammation of the white fibrous tissue, which is less serious. It is of interest to note that the rate was normal in three cases of acute chorea, a condition said to be a manifestation of an active rheumatic process.

During an investigation of 108 cases of chronic chest diseases I used this test at frequent intervals on each patient. The following is a summary of the results. If the blood sedimentation rate was raised in active pulmonary tuberculosis but remained normal when the infection was quiescent or of a low grade, the rate was either normal or subnormal in bronchial asthma, chronic bronchitis, bronchiectasis and pneumoconiosis, but was raised in the presence of secondary infection. Unfortunately the test did not help in differentiating between active phlebitis and secondary infection.

In conclusion I wish to mention several diseases in which the blood sedimentation rate was usually found to be subnormal. These included allergic diseases (eczema, hay fever, bronchial asthma), whooping cough, chronic bronchitis with much emphysema or fibrosis, congestive heart failure and jaundice. Acceleration of the sedimentation rate—for example in rheumatic carditis—may be affected by influences which retard the rate, as congestive heart failure, therefore proper interpretation of the results is essential—I am, etc.

Shotts, Lanarkshire April 10 J. A. MOORE HALL, M.D.

<sup>1</sup> A. L. Scott, *Journal of American Crosses in Canada*, *J. Roy. Soc. Med.* 53, 511-522, 1935.

### Peripheral Nerve Pain of Vertebral Origin

SIR—You have twice been so good as to discuss in the *Journal* work of mine concerned with diseases of the vertebral column (1936 2 1202 1938 1 374). On the first occasion I was impressed with the competent and objective review you gave of the work which I did in collaboration with Dr Turner. I am all the more surprised to find that the annotation on peripheral nerve pain of vertebral origin quotes one of my articles in such a way as to make it almost impossible for the reader to grasp my real meaning and has also failed to verify the points raised.

Two instances will illustrate my meaning. First the writer very rightly expresses his intense dislike of the term "discogenetic disease" which I have been using more recently. Most of us (including myself) would agree with him but I do not notice that he has suggested an alternative. It would doubtless be more correct to say narrowing of intervertebral foramina due both to anterior subluxation of inferior articular processes and to reactive exostoses at the posterior margins of the vertebral bodies as a result of degenerative thinning of intervertebral disks. The author failed to point out that I used the term discogenetic not merely for the sake of brevity but mainly to define a common disease which originating in the disks leads to a distinct clinical syndrome with pathognomonic anatomical lesions not to be confused with arthritis and spondylitis.

Secondly it is suggested that I have given credit which should naturally go to clinical medicine to roentgenological investigation. The somewhat vague invocation of the great clinicians of the past (who are not named) refers I take it to Strumpell, Pierre Marie and Bechterew. Had my previous article (*Ann intern Med* October 1936) been referred to it would have been seen that full recognition for originality of observation was given to these early investigators. Their names are nevertheless carried on stereotypically from textbook to textbook without any clear understanding of the contribution which they actually made. Professor Strumpell whom I had the privilege of knowing did not mention thinning of the intervertebral disks as a cause of disease in his lectures and publications. Pierre Marie specifically stated that the disks were not involved in the one case of spondylose rhizomelique on which necropsy was performed by A Leri. There remains Bechterew but his findings were disproved by H Turner who showed that the symptoms described were in reality due to syphilis of the nervous system. It is just too bad that Bechterew did not receive in his time such warning as has now been given me in your annotation—namely that in the presence of gross vertebral abnormalities nerve pain may result from some other cause. Incidentally I emphasized that gross vertebral abnormalities are less likely to induce neuritis than slight changes heretofore not demonstrable. It should be added in this connexion that none of these three clinicians tried to establish a definite and constant correlation between spinal disease and nerve pain. It was the rigidity of the spine in which they were primarily interested.

Before publishing my article I made a very careful study of the literature of the nineteenth century. Pathologists (Wenzel, 1824; Rokitsky, 1844; Bencke, 1896) did mention thinning of the disks but they did not describe any clinical symptoms as being associated with this condition. Only the surgeon Kocher (1896) in recording one single observation suggested that radiculitis as a result of destruction of a disk might be conceivable (*wohl denkbar*). May I therefore draw the attention

of your associate to a statement made very recently by A E Barclay of Oxford (to whom in the far future reviews will probably refer as one of the great clinicians of the past). To accept the authority of tradition is a most comfortable way of passing through life but it is not the way of progress—I am etc.

A OPPENHEIMER M.D.

Associate Professor of Roentgenology  
Chairman of the Department

American University of Beirut  
Lebanon March 2.

There is we think no real difference of opinion between us and Dr Oppenheimer as to the importance of nerve symptoms of vertebral origin. Objection was raised to the term discogenetic disease because the symptoms of nerve irritation from compression in the intervertebral foramen may proceed from other causes than atrophy of the disk whether that be traumatic or merely a senile change. Dr Oppenheimer will find a full discussion of the subject in the first volume (1931) of the *Reports on Chronic Rheumatism of the British Committee on Rheumatism* (p 128). We agree with Dr Oppenheimer that the names of Pierre Marie, Strumpell and Bechterew are repeated from textbook to textbook often without any evidence that their work is clearly understood or criticism which is especially justified in the case of Bechterew. But we had in mind rather the English clinicians such as Wilks, Hilton Fagge and Gowers. Lastly may we assure Dr Oppenheimer that his article was appreciated and suggest that criticism is a higher compliment than flattery.—ED. B.M.J.

### Control of Sulphanilamide Therapy

SIR—You have twice been so good as to discuss in the paper on the treatment of gonorrhoea with oral sulphanilamide (*Journal* November 6 1937 p 905) I would like to suggest that a differential white cell count should be undertaken as a routine when treating patients with sulphanilamide.

I treated recently a young sailor who had an uncomplicated acute gonococcal infection. All the precautions mentioned in Dr Cockkin's article were taken. For the first six days he took orally each day 4 grammes of tetracycline. On each of the next six days 12 grammes of penicillin were taken. In addition he had irrigations with 1 in 400 potassium permanganate three times a day on the first 10 days then once a day to four days. In two days the discharge was mucoid and free from gonococci and after one further day the discharge cleared up completely. After two months the test of cure was still negative (urethroscopy and complement fixation test is done). Differential white cell counts in this case were as follows:

	During Treatment			At Treatment	
	WBC	WBC	WBC	WBC	WBC
Total number of white cells	6,600	7,000	7,000	7,000	7,000
Polymorphonuclears	5	5	5	5	5
Trans. cells	3	1	0	0	0
Lymphocytes	23	20	5	20	0
Mononuclear	—	—	1	—	—
Eosinophils	6	—	5	—	—
Basophils	0.5	0	0	0	0.5

The change in the count on the twelfth day—absence of transitionals and decrease of polymorphonuclears—made the stop the treatment at that stage.

From these examinations I concluded that though the return to a normal blood count (normal for the Tropics)

was rapid in agranulocytosis might have developed in this case. The patient did his normal work and had no complaints and only a mild degree of cyanosis. This case leads me to suggest that white cell counts in patients under treatment with sulphamylamide might well be undertaken as a routine so that some indication may be given of possible toxic effects before rather than after the event.—I am, etc.

W J HOHMANN

### Treatment of Lung Abscess

SIR—In the discussion at the Medical Society of London reported in the *Journal* of April 9 (p. 803), on lung abscess no mention is made of prontosil as a remedy. A patient developed an abscess in the lower lobe of the right lung after tonsillectomy. The temperature was 104° F. and there was severe pain at the site of the abscess and cough with profuse evil smelling expectoration. After four days the temperature was normal the pain had disappeared, and expectoration was slight and not malodorous. Prontosil album, 15 grains three times a day was continued for about a week then gradually reduced, and finally discontinued after about three weeks. Slight cough with occasionally a little inspissated mucus persists but the patient feels, eats, and sleeps normally, and is putting on weight.—I am, etc.

Co Donegal April 14

C E R GARDINER

### Chemotherapy of Virus Diseases

SIR—We have read with considerable interest the letters of Drs G. M. Findlay and F. O. MacCallum, and Drs A. B. McIntyre and R. F. Montgomerie in the *Journal* of April 16 (p. 875) on the subject of prontosil and allied drugs in virus infections.

Recently we have carried out tests to determine the effect of prontosil on experimental poliomyelitis in monkeys. Two series of experiments were performed. In the first *M. rhesus* monkeys were injected with prontosil during the incubation period. In the second the drug was administered after the onset of paresis. The drug did not appear to us to have more than a slight effect upon the course of the disease. Prophylactically it failed to prevent the development of paralysis. Therapeutically it failed to prevent a fatal result.

We have also investigated the action of prontosil on infectious myxomatosis of rabbits (due to *Virus myxomatosis* Sanarelli). The drug was injected before the rabbits were infected with the virus during the incubation period and after the onset of the disease. The results were negative throughout.—We are, etc.

### Short-term Medical Commissions in the Army

SIR—In the report of the proceedings of the Parliamentary Medical Committee in the *Journal* of April 9 (p. 821) General MacArthur was misquoted as saying that a number of the first batch of short-service officers under the Warfield Fisher scheme have received permanent commissions in the R.A.M.C. Actually no such commissions have been given and the number that will be given has not been decided.—I am, etc.

FRANCIS ERMINGHAM

### Corporal Punishment

SIR—To me and probably to others who are officially called upon to administer justice the letter of Mr Victor Bonney is of much interest (*Journal* April 2, p. 757). He wisely leaves the form of punishment for wrong doing to the justices. When the laws of a community are violated and crime has been committed the wrong doer is liable to punishment, for the laws are a body of enactments or rules recognized to be binding upon the members, and infringement of which is harmful to the welfare of society and detrimental to its interests. The law breaker must be deterred, and in order to do this he is rebuked or admonished. He may be deprived of liberty, he may receive a deferred sentence, or he may be fined, but sentimentalism objects to corporal punishment. Formerly he was dealt with by the infliction of pain, deemed to be equivalent to the pain of the original offence—*lex talionis*, an eye for an eye, a tooth for a tooth—which was described as retributive punishment or revenge. In the course of many centuries our penal codes have reversed all this, but punishment of the wrong doer must be imposed in the interests of the community.

The code of honour among schoolboys to day insists upon pain as the most forceful and efficient deterrent. The erring and wayward playmate must be punished and the honour of the school vindicated. Fear of pain has a definite disciplinary value. It is Nature's warning, and a penalty is imposed for any violation of Nature's laws. I cannot realize the difference between the deterrent effect of fear in civil and criminal acts (*Journal*, April 9, p. 817) for a hurt to the individual—when carried to its logical issue—is an injury to the State, which is composed of individuals.—I am, etc.,

London W 8 April 10

ROBERT ARMSTRONG JONES

### Professor Freud

SIR—To reassure the many friends of Professor Freud in this country who might well get an alarmist idea of his condition from the description Commander Locker Lampson gave of it in the House of Commons on April 12 I should like to say that it is an exaggeration to speak of Professor Freud "as a dying man who has been deprived of liberty." Having visited him not many days ago I can testify that he was in fairly good health for his age and still at work. As for his being deprived of liberty, he is under no police detention or surveillance, though he would, of course, like other Jews, have to fulfil various formalities if he wished to leave the country.—I am, etc.

London W 1 April 13

ERNEST JONES

### The Services

#### DEATHS IN THE SERVICES

Lieutenant Colonel HENRY JOHN HUGH SYMONS M.C. I.M.S. died at Indore Central India on April 1 aged 48. He was born on October 14 1889 the elder son of Dr John Symonds of Penzance was educated at King's College Hospital and he held the post of casualty officer and took the M.R.C.S. L.R.C.P. in 1916. He took a temporary commission as lieutenant in the Royal Army Medical Corps on August 1 1916 and became captain after a year's service. On November 1 1920 he was appointed to the Indian Medical Service being ranked as captain from August 31 1917. He attained the rank of lieutenant colonel on February 12 1937. He served in the war of 1914-18 and gained the M.C. Cross on January 1 1918. He was serving in the P. Department in India.

## Obituary

### THE LATE DR LOCKHART LIVINGSTON

Dr W A Bruce Young writes from Winchester

I saw Dr Lockhart Livingston a few days before he died and with others of his colleagues, deeply regret to know he has left us. He did not seem to have ever got over the loss of his wife a few years ago though he seemed pretty cheerful when I saw him in his room in the nursing home a fortnight ago. He was one of the fast-diminishing number of those to whom many of us engaged in public health work are so much indebted for almost pioneer work—old country practitioners who combined with their heavy day and night work the often thankless task of inculcating ideas of elementary hygiene in those for whom they worked. Dr Livingston was honoured and respected by all who knew him whether lay or professional as one who happily combined those qualities so often found in our country doctors—sympathy and care for the welfare of their patients together with a liberal and open minded interest in things professional. He was the tried and trusted Representative of the Winchester Division for very many years and I have reason for knowing that their interests and those of the B.M.A. as a whole were always held very dear by him. He did us good and faithful service.

Dr RALPH CLARKE BARTLETT who died in Southampton on March 10 had been medical officer of health for Romsey, Hants until his retirement from practice five years ago. He was born at Brighthelm, Devon and received his medical education at University College Hospital, London. In 1891 he obtained the diplomas M.R.C.S. L.R.C.P. and was later obstetrical assistant at University College Hospital. He then practised in Australia for some years holding the post of honorary medical officer to Cowra District Hospital, New South Wales. He returned to England about forty years ago and took over a practice in Romsey. He was appointed a Justice of the Peace for the Borough, and was medical officer of health. He was a fine athlete and organized lawn tennis tournaments. He was a member of the Southampton Medical Association and was highly esteemed by his colleagues and large circle of patients in South Hampshire. The funeral service at Romsey Abbey on March 12 was attended by many representatives of local interests and activities. Dr Bartlett became a member of the British Medical Association in 1919. He is survived by his widow, two sons and one daughter.

Dr NADIR HORMAZ SHAW GANDHI died at the North Stafford Royal Infirmary on March 30. Descendant of an old Parsi family, he was born fifty-nine years ago at Neemuch in Central India and was educated at Jodhpore and Allahabad where he took his M.A. with honours and gold medal in chemistry while still in his eighteenth year. Securing the Sir D. J. Tata scholarship he came to England to compete for the Indian Civil Service. He entered Caius College, Cambridge and graduated B.A. in the Natural Sciences Tripos of 1902 but just failed to secure a place in the I.C.S. greatly to his disappointment. He then took up medicine, joined the London Hospital and took the English Conjoint diplomas in 1906. After practising in London for some time he went to Hanley and Bucknall near Stoke. There after some years of the dry-bread stage of general practice success at last came to him and by hard work, unstinted devotion to his duties, charm of manner and generous nature he built up a very large practice. For several years he held

the post of M.O.H. to the Stoke Rural Council and was a member of the British Medical Association for nearly thirty years. A year ago sorrow came to him in the sudden loss of his wife and he met his own end with courage. Preceding the cremation at Secport the funeral service was conducted at the Bucknall Parish Church which was thronged by large numbers of his patients. In the words of the vicar: "He was a man who helped people at times when they most needed help and that well might be his epitaph."

Dr WILLIAM CONWAY GENT who died suddenly on April 1 at Southbourne, Bournemouth, aged 66, was educated at Magdalen College School and then went on to study medicine at Bristol and Edinburgh qualifying L.R.C.P. and L.R.C.S.Ed. and L.R.F.P.S.Glasg. in 1894. Dr Gent joined the British Medical Association in 1894. In his younger days he was a keen rider to hounds and an enthusiastic golfer. Later he had been living in retirement at Southbourne. He was married twice and leaves a widow and one son. Surgeon Lieutenant-Commander J. C. Gent R.N.

We regret to record the death on April 2 at Hove of Dr ARCHIBALD DINGWALL, aged 75 years. He was born at Auchterless in 1863 and received his medical education at Aberdeen University where he took the degrees of M.A., M.D. and C.M. He practised at Fraserburgh later in Wales and at Clapham Park, London, finally retiring to Hove. He was gazetted Captain R.A.M.C. during the great war serving in the Isle of Thorns area. He was especially interested in ambulance work and in work among the boy scouts. Dr Dingwall was a member of the British Medical Association for nearly fifty years. He was also a Mason. His contributions to medical literature were few. He wrote an article in the *British Medical Journal* in 1912 on "Gastro-intestinal Haemorrhage in a Newborn Infant" and it is interesting to note that he followed with interest and assistance the career of the child referred to who is now a medical graduate of Edinburgh University. Dr Dingwall was of a singularly retiring disposition, loving and loved by all with whom he came in contact. He leaves a widow and two daughters. The funeral was private and attended only by members of the family and a few old medical friends. Among the latter was one from the local Division of the B.M.A. in affectionate memory of an honoured colleague.

The death took place on April 4 in Edinburgh of Dr ANNE MERCER WATSON, who was one of the earliest women to enter the medical profession in Scotland. Dr Watson practised for many years in Aberdeen and had lived at 12 Webster Coates Avenue, Edinburgh, since her retirement. She was born at Dundee in 1862 and attended a medical course at University College, Dundee, and the Medical College for Women in Edinburgh, where she took the triple qualification in 1899. After periods of residence in the Royal Infirmary at Dundee and in the Victoria Hospital for Chest Diseases at Edinburgh she set up practice in Aberdeen where she was in partnership with Dr Laura Stewart Sandeman and was visiting medical officer of the Morningfield Hospital. During the war Dr Watson acted as an auxiliary of the R.A.M.C. and was prominently identified with the recruitment of the Edinburgh section of the W.A.A.C. She had been a member of the British Medical Association since 1900 and when the Association met at Aberdeen in 1914 she acted as secretary of the Section of Medical Science.

Dr FRANK BENJAMIN LEWIS who died on April 10 at his home in London Road, St. Leonards-on-Sea, was born in Surrey on April 29, 1867, the son of Thomas Lewis and studied medicine at the London Hospital. In 1892 he qualified with the licence of the Society of Apothecaries of London and in the same year took the L.R.C.P. and L.R.C.S.Ed. and L.R.F.P.S.Glasg. Dr Lewis was for

in many years medical officer of health under the Hastings Rural District Council public vaccinator and surgeon to the Buchanan Hospital, he was also a Justice of the Peace for Sussex. He joined the British Medical Association in 1893 and served as Representative of the Hastings Division at the Annual Representative Meeting in 1919.

The death occurred on February 6 of the Danish radiologist JENS JUUL at the early age of 41. He had already made a distinguished career for himself and had recently been put in charge of the radium station in Copenhagen after having served several years apprenticeship in the radiological departments of various Danish hospitals. He was particularly interested in the treatment of cancer of the mouth, throat, and oesophagus, and had elaborated a radiological technique which now bears his name in Denmark.

Dr J. V. HULIKRANIZ who died on February 14 at the age of 75 was lecturing when an attack of coronary thrombosis proved suddenly fatal. He was Professor of Anatomy in the University of Uppsala from 1899 to 1930 and he published many studies, among which his investigations of the movements of the diaphragm deserve special notice. His anthropological studies were also of a high order.

The following well-known foreign medical men have recently died: Dr OTTO NÄGELI professor of internal medicine and director of the Medical Clinic at Zurich, and an authority on diseases of the blood, aged 67; Dr HERMANN WALTER professor of surgery and orthopaedics at the Wilhelm University at Münster, aged 45; Dr HANS ALLENBURGER extraordinary professor of neurology and head of the physiological department of the Neurological Research Institute Breslau, aged 36; Dr MAURICE GÉRARD professor of clinical urology at Lille; Dr ENRIQUE BASTOS of Lisbon, an eminent Portuguese urologist; Professor MAXIMILIAN ROSE of Vilno, author of important work on the structure of the brain; Professor GEORG DEYCHIL PASCHA, formerly director of the Gulhane Hospital at Constantinople and an authority on tuberculosis and leprosy; Professor FRIEDRICH VON KRTGER formerly director of the department of physiological chemistry of the Physiological Institute of Rostock; Professor FRITZ KAYSER an eminent military surgeon of Cologne, aged 71; Professor GAETANO SAMPIETRO director of the Giromont laboratory at Rome, aged 62; Professor GUSTAVE DELAY dean of the Lausanne Medical Faculty from 1932 to 1934; Dr ETIENNE BARRAL honorary professor at the Lyons Faculty of Medicine and Pharmacy and corresponding member of the Académie de Médecine; Dr JOSEPH ARROU an eminent Paris surgeon, aged 77; and Dr DOMENICO TADDEI director of the surgical clinic at Florence and joint editor with Dr Guido Izzi of *Rivista Internazionale di Clinica e Terapia*, aged 63.

At the last quarterly court of the directors of the Society for Relief of Widows and Orphans of Medical Men with Mr V. Warren Low, president, in the chair, the annual report and financial statement for 1937 to be presented at the annual general meeting on May 25 was submitted and approved. During the past year £4,702 was distributed in grants to widows and orphans. There was a surplus of income over expenditure of £112 due partly to the inability of the society owing to the increase in the number of widows in receipt of grants to make Christmas presents to them. This year the society celebrated its 170th anniversary of its foundation and it is suggested that a festival dinner should be held on October 27. Here it only seemed to necessitous widows and orphans of deceased members. Membership is open to any registered medical man who at the time of his election is residing within the limits of the County of London. Full particulars may be obtained from the secretary at 11 Chandos Street, Cavendish Square, W.1.

## Medical Notes in Parliament

In the House of Lords on April 12 the Lords' amendments to the Infanticide Bill were reported. On April 13 the Bill was read the third time and passed.

On the same day the Royal Assent was given to the Dogs Amendment Act, the Trade Marks Act, and the Rating and Valuation (Postponement of Valuations) Bill.

The Increase of Rent and Mortgage Interest Restrictions Bill was read a third time in the House of Commons on April 13.

The Road Haulage Wages Bill, "to make provision with respect to the remuneration of persons employed in connexion with the mechanical transport of goods by road" was presented to the Commons by Mr Ernest Brown on April 13, and read a first time.

Mr Ernest Brown announced on April 14 that he had received the report of the Committee on Holidays with Pay. The report was unanimous, and he hoped to publish it soon after the House resumed on April 26.

Sir John Simon has appointed a committee, under the chairmanship of Mr C. T. Le Quesne, K.C., 'to examine and report on the complaints which are made as to the position of unmarried women under the Contributory Pensions Acts, and on the practical questions which would arise if the age at which old age pensions under those Acts are payable to unmarried women were lowered'.

The House of Commons will reassemble on April 26, when Sir John Simon will open the Budget.

### Foot-and-Mouth Disease Outbreaks

In the House of Lords on April 12 Lord NUNBURNHOLME called attention to the recent outbreaks of foot and mouth disease, and asked if the Government had considered taking other measures to limit transport and access to any of the infected areas.

The Earl of FEVERSHAM said it was disappointing that, after the outbreak of the disease in the South Eastern Counties last October had been wiped out, this fresh series of outbreaks should have begun. So far as the Ministry of Agriculture could see, the outbreaks which began on March 25 had no connexion with the last epidemic. Several different types of the disease existed, but there were indications that the present epidemic had no concern with the type of the disease of last autumn and winter. At any rate, the disease in its present form appeared to take a longer time to show its presence in the animals. Another difference was that in the last epidemic a series of outbreaks appeared simultaneously in many parts of the country. The disease then arrived without warning and without evidence of definite centres from which it spread. This led the Ministry to connect that epidemic with the migration of birds from the Continent which was going on at that time.

In the present case, although the outbreaks had occurred in widely separated places, the evidence led them to believe that infection was picked up at certain definite centres, certain important markets in the Midlands which had together distributed stock over the greater part of the country. That meant that there was a longer period of warning in order to check any further distribution of the disease by movement of animals and to obtain a breathing space in which they could track down every single animal that might have been exposed to infection. The Ministry decided that they must impose a standstill order on the whole of England with the exception of the far north and the far west.

Since the standstill order was imposed on April 4 four new centres of disease had appeared. The facts so far available indicated that the actual spread of infection would not prove so serious as at first was anticipated. It within the next few days this view was confirmed and the Ministry were satisfied that the spread of the disease had been checked. They anticipated that a substantial reduction of the controlled area would be possible even if it was impossible entirely to withdraw the order covering those parts closest to the infected areas.

The Ministry were aware that in some countries on the Continent more severe restrictions had been imposed. The disease was still going on in Germany and recently the Ministry had had information to show that it was getting worse. From March 1 to March 15 there were 25,000 outbreaks in Germany almost twice as many as in February and over eighty times as many as we had in the whole of the financial year 1937-8. On the Continent the slaughter policy which we could adopt because we lived on an island was not practicable and infection was not wiped out as it was here.

Some of the measures advocated by Lord Nunburnholme might not be quite as effective as was suggested and might even make the position worse. They might close down their parish life but they could not close down the life of their birds ground game rodents or vermin. The Government preferred to rely on the existing restrictions and on the slaughter policy which strangled the disease at its birth rather than on measures the inconvenience of which would outweigh any possible advantage which might be derived from them.

VICOUNT DAWSON OF PENN asked where the evidence that birds were associated with this infection was accumulating and broadly what it amounted to and whether there was any particular bird which was thought to be guilty in this respect.

The Earl of FEVERSHAM said it was thought that the outbreak in the autumn and winter which started in East Anglia and eventually found its way to the West of England was connected with migratory birds which first landed on the East Coast and in the course of their usual flight went west. The research committee which had been set up to deal with foot and mouth disease had had much evidence submitted to it of that kind, and it was thought that in particular starlings might have been the means of carrying the virus. Up to the present he had no particular information which led him to think that this evidence supplied during the winter carried any conclusive proof. There was no evidence up to the present to show that the spread of the disease was due to migratory birds more than to the movement of any ruminating animal. The danger of the disease at the moment lay in one fact—that a large number of sheep—infected stock—were sold in Banbury Market and went in the normal course of marketing operations to all parts of England except Durham Northumberland Westmorland Cumberland Devon and Cornwall.

### Public Telephones and Tuberculous Infection

MR R. GIBSON asked the Postmaster General on April 11 if experiments had been made by officials of his department to discover whether tubercle germs were present in the mouth pieces of public telephones which were cleaned and those which were not cleaned respectively every morning. Major TAYLOR replied that investigations of the kind in question had been repeatedly undertaken in this country and in the United States by independent bacteriologists at the instance of public health and other authorities. They were unanimous in concluding that the risk of tuberculous infection from the use of the telephone was negligible. This conclusion was verified by the Post Office Medical Department by means of separate research.

### Medical Volunteers for A.R.P. Services

On April 12 the Prime Minister was asked by a Member what had been the response to the call for medical and nursing volunteers for the various air raid precaution services. Mr

CHAMBERLAIN replied that while figures were not available for the whole country recruiting for first aid work was satisfactory except in a few areas.

MR BULL asked on April 14 in what manner the services of doctors were being enlisted for duty in connexion with air raids and whether those who had offered their services for this work had been allocated to specific districts. Mr LLOYD replied that doctors would be required in connexion with air raid precautions primarily for supplementing hospital staff. The Home Secretary was consulting the Minister of Health on the whole question of hospital provision. In the meantime the scheme for the training of doctors in anti gas measures was proceeding steadily. Mr SANDYS asked whether it was proposed to send a proportion of hospital patients from the more vulnerable areas to other parts of the country and if so what arrangements had been made in the case of London. Mr LLOYD replied that this was one of the matters in connexion with hospitals about which the Home Secretary was in consultation with the Minister of Health. He recalled the statement that the survey of London would be completed in a few weeks.

### Voluntary Hospitals and A.R.P.

On April 12 Mr LOUIS SMITH asked the Home Secretary whether his attention had been called to the fact that when would fall on voluntary hospitals if they took as they were expected to do the fullest measures of air raid precautions to protect their patients and staff whether he would make inquiries as to the views of hospital managements generally on this important issue and whether he would then consider the grant to the hospitals of State assistance to ensure the necessary protection. Mr GEOFFREY LLOYD replied and said that voluntary hospitals like other institutions were expected to take such measures as were reasonable in the circumstances for the protection of their patients and staff. There would however be some hospitals which would be used as casualty clearing stations under a local authority's scheme approved by the Home Secretary. In such cases the local authority could contribute to any special expenditure involved in their use and such expenditure if approved would in proper cases rank for grant under the Acts.

Colonel NATHAN asked when the hospitals which were to be used as casualty stations would be told that that was so. He also asked with regard to other hospitals whether it was intended that the funds subscribed by the charitable public for the cure of disease and helping the afflicted should be used for the protection of premises against air raids. Mr LLOYD replied that a good many hospitals would undoubtedly fall under the class which he had described. The Ministry of Health was at present engaged in a survey of the hospital accommodation of the country from the air raid precautions point of view.

Colonel NATHAN asked if Mr Lloyd was not aware that the great voluntary hospitals of London were at present without any information at all of what was expected of them in the event of air raids and that their efforts to obtain information from the Home Office or else here had been fruitless.

MR LLOYD: I understand that the survey of London will be completed in a few weeks.

### School Accommodation for Defectives

MR ELLIOT replying to Mr KIRKWOOD on April 12 said it was proposed to accommodate physically and mentally deficient children in the same building in the College Street School Dumbarton. This arrangement was in accordance with terms of paragraph 26 of the Department's Circular No. 10 dated September 1, 1937. Arrangements would be made to keep the two classes of children separate in all respects—class tuition meals and recreation.

MR MUIF asked if Mr Elliot was aware that under a condition of times would not be tolerated in England and if he would endeavour to bring Scotland up to the standard of England. Mr ELLIOT replied that Mr MUIF was under a misapprehension. It was the common practice in England and

Wales and Scotland to provide on the same site, and in many cases under the same roof a school for mentally defective children as well as physically defective children. Replying to Mr Westwood Mr Elliot said he thought that this practice was desirable in the interests of education and of the children. It was recommended in the circular issued by the Department to the education authorities.

### Insulin Treatment of Schizophrenia

Sir KINGSLEY WOOD issued Mr Rhys Davies on April 13 that he would endeavour to place in the library of the House a copy of the report of the international conference on the insulin treatment of schizophrenia. At least twelve public mental hospitals and six private institutions in this country were applying insulin treatment. Mr RHYS DAVIES asked whether steps were being taken to train a sufficient number of medical men and mental nurses in the technique of this treatment, whether the treatment was in vogue in any private mental hospitals and if so what were the results? Sir KINGSLEY replied that it was not practicable within the limits of an oral answer to deal with results of treatment and training in the technique.

### Ante natal Clinics of Local Authorities

Mr JOEL on April 12 asked the Minister of Health how many towns of over 20,000 people were without ante-natal clinics and what action he was taking in each of these cases to induce the local authorities to take remedial measures. Mr BERNAYS said that out of 230 towns with over 20,000 people, the local authorities of which were themselves welfare authorities for this purpose only eight were without ante-natal clinics. In each of these cases either suitable alternative provision was available or ante-natal clinics were about to be established. In the case of seventy-seven towns of over 20,000 people which were included in the areas of county councils as welfare authorities the information was not readily available, but he would obtain the information Mr Joel desired.

Mr LEACH asked if the Minister would undertake to publish the names of the authorities which had been so negligent.

Mr BERNAYS: As they are about to provide ante-natal clinics I do not think that would be desirable.

### Health of Ex-service Men

On April 14 on the motion that the House of Commons adjourn over Easter till April 26 Mr F. B. SIMPSON opened a debate on the provision and administration of pensions, with particular reference to disabled ex-service men. He said that of 442,317 persons receiving disablement pensions at the end of 1937 64 per cent received 100 per cent pensions, 24.2 per cent received 30 to 40 per cent pensions, and 45 per cent received pensions of 20 to 30 per cent. The British Legion had gone into the problem of the prematurely aged ex-service man. The Legion was convinced that the health of a number of ex-service men had broken down as a result of the rigours of war service although it was impossible to substantiate by medical sequence a direct connexion with such service. Laymen were naturally convinced that there was a relation between the loss of one eye in the war and the subsequent loss of the other, but Mr Simpson cited a case where the medical experts said there was no connexion.

Mr BELLINGER asked for an inquiry.

Mr KELLY drew attention to the number of ex-service men who were patients in mental hospitals. These men were mental ill because of their service. The country would not then any money required for treatment or research which might afford some hope for these men.

Sir HENRY MORRIS JONES said men who knew about medical science were discouraged on bringing cases to the Ministry because of the difficulty in getting a medical review of their case. He had come to the conclusion that it was almost impossible to get a review of a case although he knew this case was a case of considerable importance. He asked the Minister

of Pensions to set up an inquiry into the medical aspects of these cases. Medical science had changed in the last twenty years. There was, for example, a different point of view as regards the heart and chest. Could not the Minister set up a medical committee to review aspects of the medical complaints? On surgical cases a more definite line could be taken when the wound was seen.

Mr RAMSBOTHAM said the subject of war pensions had been discussed before Christmas. The further debate of that day had raised no fresh facts for him to answer. He was prohibited from granting entitlement to a pension unless he had a medical certificate. To ask him to indulge in more laudable was to press him to ask his medical advisers for medical certificates which might not represent the honest view of the cases. The House would never ask him to do that. He agreed that the pensioner should have the benefit of the doubt. In the past twelve months he had no such complaints as that made by Sir Henry Morris Jones. He would be delighted to confer with Sir Henry, who must know that it was a system of independent medical experts. There were men of the highest repute in the medical profession, selected from a panel of the Royal College of Surgeons and the Royal College of Physicians. Mr Ramsbotham added that he made constant use of them. The average age of ex-service men today was about 50 and men of that age were subject to ailments resulting from the wear and tear of civil life. For that reason the Ministry now got many complaints of heart trouble, rheumatism, and chest trouble which were in exactly the same proportions among people in civil occupations. Every man suffering from disabilities which he thought due to war service was given by the Ministry of Pensions every opportunity to establish his case. The Ministry made researches with the approved societies, with chemists, shops, and with employers for evidence that the complaint had a continuous history. In many cases those links could not be discovered, and then it must be the case that a medical adviser could not say the present disability was the result of an injury or wound suffered in the war.

The House passed to discussion of other subjects and then adjourned for the Easter Recess.

### Problems of Milk Supply and Consumption

Wing Commander JAMES asked Sir KINGSLEY WOOD on April 14 whether, having regard to the divergence of opinion upon matters of fact expressed by various authorities upon bovine tuberculosis, pasteurization, and other matters affecting the supply and consumption of milk, he would appoint a committee to investigate and to report upon these problems. Sir KINGSLEY replied that the facts with regard to bovine tuberculosis and pasteurization in relation to the milk supply were sufficiently well established by inquiries such as that of the Committee of the Economic Advisory Council on Cattle Diseases.

Captain HILGERS: Is the Minister going to do anything to discourage biased propaganda on the question of pasteurization by the medical authorities?

Sir KINGSLEY WOOD: That is a different matter.

### Additional Factory Inspectors

In view of the passing of the Factories Act of last year and of other developments a scheme has been worked out which will have the effect of increasing the strength of the factory inspectorate by sixty-two or about 23 per cent over a period of three years. The scheme includes the appointment of an additional deputy chief inspector, and an additional superintending inspector to take charge of a new district which is being created in the Midlands, and the addition of three medical, one electrical and seven engineering inspectors. This announcement was made by Mr Lloyd on April 14.

Psychological Treatment of Prisoners—Sir R. LLOYD asked the Home Secretary who appointed the special committee of investigation into the psychological treatment of prisoners.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended April 9, 1938

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland Median values for the last 9 years for (a) and (b)

Figures of Births and Deaths and of Deaths recorded under each infectious disease, are for (a) The 125 great towns (122 in 1937) in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns (9 in 1937) in Northern Ireland

A dash — denotes no cases, a blank space denotes disease not notifiable or no return available

Deaths from puerperal sepsis  
Include primary puerperal sepsis for England and Wales, London (administrative county) and Northern Ireland

## EPIDEMIOLOGICAL NOTES

## Enteric Fever

During the week under review 2 cases of enteric fever were notified in Cardiff these belong to an outbreak of paratyphoid fever in which at the time of going to press there have been 7 cases 4 in children and 3 in adults. So far the cause of the outbreak has not been ascertained.

## Diphtheria and Scarlet Fever

In England and Wales the decline in the incidence of diphtheria and scarlet fever continues both diseases are still more prevalent than they were last year but whereas the incidence of diphtheria is higher than in the previous nine years that of scarlet fever is lower. On the other hand the London figures for both diseases show a slight increase over those for the previous week as in England and Wales diphtheria is more prevalent and scarlet fever less prevalent than in the last nine years. In Scotland, Eire, and Northern Ireland increases are recorded during the week, with the exception of diphtheria in the last-named country, in which 25 cases were notified compared with 38 in the previous week.

## Measles and Whooping-cough

In the 125 Great Towns in England and Wales there were 36 deaths from measles, compared with 38 in the previous week, of these 15 occurred in London 4 in Manchester and 3 each in Barnsley, Reading and Salford. The prediction made last week that measles is on the wane in London is confirmed by the figures for the week under review 1,895 cases were reported from the L.C.C. elementary schools compared with 2,095 in the previous week, and the average daily admissions to the L.C.C. fever hospitals dropped from 92 to 78. The number of cases of measles under treatment in these hospitals on Friday, April 8 was 2,241 compared with 2,339 on April 1. On the same date there were in the L.C.C. hospitals 1,160 (1,128) cases of diphtheria 843 (838) cases of scarlet fever and 291 (312) cases of whooping cough. The figures in parentheses refer to the numbers recorded in the previous week. Notifications in the eleven metropolitan boroughs in which measles is notified were for the week ended April 9 833 (1,113) distributed as follows: Battersea 128 (144) Bermondsey 88 (76) Finsbury 27 (30) Fulham 41 (77) Greenwich 99 (136) Hampstead 55 (47) Lambeth 188 (264) St. Pancras 110 (123) Shoreditch 51 (33) Southwark 115 (124) Stepney 51 (37). The figures in parentheses denote the numbers in the previous week. In Scotland 1,044 cases of measles were reported compared with 1,421 in the previous week the figures for Glasgow were 549 (692) for Dundee 179 (224) Aberdeen 81 (246) and Paisley 42 (29). During the week under review there were in the principal towns in Scotland 23 deaths from measles compared with 19 in the previous week of these 16 occurred in Glasgow 5 in Dundee 1 in Edinburgh and 1 in Ayr. In Northern Ireland there were 30 cases of measles (all in Belfast) compared with 80 in the previous week and 3 deaths (all in Belfast) a decrease of 5 on the previous week. There were no deaths from measles in Dublin in the previous week there were 2.

Compared with last week there were fewer deaths from whooping cough in England and Wales. London, Eire and Scotland while in Northern Ireland the same figure 1 was recorded. Whooping cough mortality was much lower in England and Wales and in Scotland than in the corresponding week last year.

The Ministry of Health announces that the Committee of Inquiry into the Anti Tuberculosis Service in Wales and Monmouth will resume its sittings in the City Hall Cardiff on Monday next April 25 at 11 a.m.

## Medical News

The King has granted Mr Cecil Rowntree F.R.C.S. authority to wear the Order of Officer of the Order of Leopold conferred upon him by the King of the Belgians and the Order of Chevalier of the Legion of Honour conferred by the President of the French Republic.

A meeting of the Chelsea Clinical Society will be held at the Hotel Rembrandt, Thurloe Place, S.W. on Tuesday April 26 at 8.30 p.m. when Dr L. I. M. Castleden will open a discussion on 'The Uses of Dyes in Medicine'. The meeting will be preceded by dinner at 7.30 p.m.

Professor Henry Cohen will deliver the annual oration before the London Jewish Hospital Medical Society at Sussex Place N.W. on Sunday May 1 at 8.30 p.m. His subject is 'A Century Ago—A Medical Retrospect'. The chair will be taken by the president Professor Samson Wright. Admission is by ticket only obtainable from the honorary general secretary Dr Max Sorsby, London Jewish Hospital, Stepney Green E.1.

The annual meeting of the British Association for the Advancement of Science will be held this year at Cambridge from August 17 to 24 under the presidency of Lord Rayleigh F.R.S. The following are the section presidents: Section A Mathematical and Physical Sciences Dr C. G. Darwin F.R.S. B Chemistry Professor C. S. Gibson F.R.S. C Geology Professor H. H. Swinerton D.Sc. D Zoology Dr S. W. Kemp F.R.S. E Geography Professor T. G. Smith Taylor D.Sc. F Economics Mr R. F. Harrod G Engineering Professor R. V. Southwell F.R.S. H Anthropology Professor V. Gordon Childe D.Sc. I Psychology Dr R. H. Thouless K Botany Professor W. Stiles F.R.S. L Education Mr John Sargent M Agriculture Professor R. G. Stapledon.

Owing to the prolongation of the war in Spain the fifth congress of the Latin Medical Press which was to have been held in Lisbon during the Easter holidays has been postponed until next autumn when it will be held at Lisbon from September 29 to October 2 under the presidency of Professor Reynaldos dos Santos. Further information can be obtained from the general secretary Professor Armando Narciso Restauradores 48 Lisbon or Dr Pierre 52 Avenue de Breteuil Paris VIe.

In our advertisement columns this week the Corporation of London invites applications for the office of Medical Officer of Health for the Port of London. The commencing salary is £1,500 per annum rising to £2,000 per annum.

An award of the Dr Jessie Macgregor Prize in Medical Science will be made in July next to the applicant who presents the best record of original work in the science of medicine. Such work may be published or unpublished but must not have been published earlier than three years prior to July 1938. The value of the prize is about £20 and is open to medical women who are graduates in medicine of the University of Edinburgh or who have taken the triple qualification and who before becoming qualified have studied medicine for at least one year in Edinburgh. The successful applicant shall within six months following the award deliver a lecture to the medical profession in Edinburgh on the subject of the work for which the prize has been awarded. Such lecture to be entitled 'The Dr Jessie Macgregor Lecture'. Applications marked 'Dr Jessie Macgregor Prize' must reach the Convener of Trustees Royal College of Physicians Edinburgh 2 not later than June 30.

Two Sir Milom Rees Scholarships for one or two medical practitioners of £100 each to Port Rees Preparatory School Broadstairs have been awarded to P. Burrows son of Dr H. Burrows and to P. King son of Dr P. A. H. King.

The Robert Jones Gold Medal and Prize of £20 of the British Orthopaedic Association for 1937 has been awarded to Mr H. Jackson Burrows for his essay on 'Coxa plana'.

Dr George B Bitten of Dulwich a pioneer radiologist, and Mrs Bitten received a presentation from their medical and other friends at a reception on the occasion of their golden wedding on April 9

The National Safety First Association held its annual industrial safety conference at New College Oxford on April 8, 9 and 10. The subjects discussed were the safety education of the new employee, the Factories Act 1937, modern practice for fixed machine guards, and works safety propaganda. The complete proceedings including reports of discussions will be published shortly from the offices Terminal House 52, Grosvenor Gardens SW1.

Dr Richard Pfeiffer for many years professor of hygiene at Breslau and discoverer of the influenza bacillus in 1892 celebrated his eightieth birthday on March 27.

A new French 30,000 ton ocean liner which is to run between France and the Argentine next year, has been named *Pasteur* by Mme Pasteur Vallery-Radot, wife of the scientist's grandson.

## Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, BMA HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, BMA House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS if reprints are required; if proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, BMA House, Tavistock Square, W.C.1.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are:  
EDITOR OF THE BRITISH MEDICAL JOURNAL: Autology, Westcent, London.

SECRETARY: Mediscera, Westcent, London.

The address of the BMA Scottish Office is 7 Drumsheugh Gardens, Edinburgh (telegrams: Associate, Edinburgh), telephone 24361 (Edinburgh), and of the Office of the Irish Free State Medical Union (I.M.A. and B.M.A.) 18 Kildare Street, Dublin (telegrams: Bacillus, Dublin), telephone 62550 (Dublin).

## QUESTIONS AND ANSWERS

### "Typhoid Mary"

Dr J. D. ROBERTSON would be glad to know of any account of this celebrated carrier published after the description of her case by Major George A. Soper in the *Military Surgeon* 1919, 15, 115.

### The Elder Twin

E. H. writes: "Can any reader help me to find the correct descriptive word for the elder of twins? I have searched in many available books of reference and have inquired in various directions, but unsuccessfully."

### An Internal Sanitary Pad

WOMAN DOCTOR writes in reply to G.P. (*Journal* April 16, p. 840): "Although not a gynaecologist, my observations on the internal sanitary pad may be of use to G.P. I have found them very unsatisfactory in that they cause a constant feeling of fullness and stimulation in the vagina. This is particularly noticeable in the case of the nullipara with a narrow vagina. For obvious reasons these internal pads cannot be used by a virgin as insertion would be extremely difficult, if not impossible. They also tend to cause irritation as the pressure on the rectum seems to be too great for complete relaxation. They may be used for a short time if some particular case makes it specially desirable."

## LETTERS, NOTES, ETC

### Destruction of Bugs

Dr N. PINES (London E.1) writes: "May I mention how bugs were destroyed, nearly always successfully, in pre-war Russia? Walls were invariably stripped and whitewashed with CaCl<sub>2</sub>, all cracks in them being previously washed out with kerosene and stopped with some material after that. The cracks in the floors were also washed out with kerosene and stopped after that with some material. Furniture and fittings were removed, taken to pieces if possible, liberally washed with kerosene and afterwards with boiling water and soap. Beddings and garments were disinfected in the ordinary way by formalin vapour. Bugs are very elusive and not only the bedrooms but the whole of the premises must be carefully examined for their traces, and in cases of doubt treated in a similar way."

### Polydactylism

Dr S. HARTILL (East Cowes) writes: "The following is an interesting example of supernumerary toes and fingers."

The diagram, in which N represents normal offspring, indicates quite clearly the incidence of this condition in three generations.

### Treatment of Pneumonia

Dr H. W. HALES (London W.1) writes: "I have only just seen Dr Nott's letter in the *Journal* of January 22 (p. 203). I should like to endorse several of his statements. In my experience limited to some seventy odd cases, colonic lavage with potassium permanganate is the most valuable treatment ever introduced for pneumonia. I am sure that the chief factor in pneumonia is intestinal toxæmia, and that the chief cause of death from this complaint is this cause acting on the heart. On four occasions I have reproduced pneumonia during a course of detoxication by potassium permanganate colonic lavage, pyretic treatment, and reduced diet in patients who have had the disease on two or three occasions previously. In each case the illness only lasted twenty-four hours or so, but the signs in every instance were typical. Knowing that this statement might reasonably be questioned by the profession, I asked certain professional colleagues of mine to see the patients in question. I expressed entire agreement with my views, and was not surprised at seeing the patients sitting up in bed breathlessly with half the lung solid and no sign of toxæmia. This pneumonic reaction also seems to indicate the true origin of the disease. One further point. The patients treated by Nott's method contain chloride in the blood, chlorides remain normal, and the patients throughout the disease. I feel that the chloride deficit of pneumonia and the sweating deficiency of the crisis are produced by an intestinal toxæmia on the blood chlorides and upsetting the skin."

### Medical Golf

The spring meeting of the Scottish Medical Golfing Society was held at Bramshott Golf Club on April 10, with the following results—*Medal Round*: Dr A. F. Adams 94 less 14 = 80, and Dr Mather Thomson 90 less 10 = 80, tied for first place. *Foursomes*: 1st Dr A. S. Paterson, Dr E. L. Bartleman 1 down, 2nd Dr D. Macdonald, Dr R. K. Trail 3 down, Dr A. J. Buchan and Dr Findlay 3 down.

Evans, Sons, Lescher, and Webb Ltd. have received a grant from their Biological Institute at Runnymede for the *Evans Journal*.

## POSTGRADUATE NEWS

The Fellowship of Medicine announces the following course of postgraduate medicine at Maudsley Hospital April 25 to May 28, proctology at Gordon Hospital May 2 to 6, dermatology at St John's Hospital May 2 to 28, thoracic surgery at Brompton Hospital May 16 to 20, plastic surgery at various hospitals May 11 and 12, gynaecology at Chelsea Hospital May 23 to June 3. Courses in preparation for the M.R.C.P. examination in July will be as follows: clinical and pathological at National Temperance Hospital Tuesdays and Thursdays 8 p.m. May 31 to June 16, chest diseases at Brompton Hospital Tuesdays and Fridays 5.15 p.m. May 10 to June 24, heart and lung diseases at London Chest Hospital Wednesdays and Fridays 6 p.m. June 1 to 24, neurology at West End Hospital June 13 to 25, pulmonary tuberculosis at Preston Hall June 25. Week-end courses occupying the whole of a Saturday and Sunday will be given as follows: children's diseases at Infants Hospital April 10 and May 1, chest diseases at Brompton Hospital May 7 and 8, general surgery at Princess Beatrice Hospital May 14 and 15, physical medicine at St John Clinic and Institute of Physical Medicine May 21 and 22, obstetrics at City of London Maternity Hospital June 11 and 12, radiology at Royal Cancer Hospital June 18 and 19. The Fellowship of Medicine's dinner-dance will take place at Claridge's Hotel on May 19. All members of the medical profession both at home and from overseas will be welcome. Tickets can be obtained from the Fellowship of Medicine, 1 Wimpole Street W.1 or from any member of the ladies' committee.

The Joint Tuberculosis Council announces that Dr. Peter W. Edwards, medical superintendent of the Cheshire Joint Sanatorium, is prepared to continue his series of short intensive postgraduate courses of a practical nature on modern methods of therapy in tuberculosis of the respiratory system with special reference to collapse therapy. In the sanatorium there is abundant material for the demonstration of artificial pneumothorax and allied procedures. Methods of sanatorium administration will also be demonstrated. Dr. Edwards is prepared to hold courses from May 2 to 4, June 27 to 29, and September 26 to 28. The fee for a course is £2.75 which includes lunch and tea at the sanatorium. All inquiries should be addressed to Dr. William Brand, honorary secretary for postgraduate courses, Joint Tuberculosis Council, 8 Christ Church Place, Epsom, Surrey.

A course of lectures on pathological research in its relation to medicine will be given in the lecture theatre of the bacteriological department of the Institute of Pathology and Research, St. Mary's Hospital W, on Tuesdays at 5 p.m. from April 26 to June 14 inclusive. The lectures are open to all members of the medical profession and to all students in medical schools without fee. Details will be published in the postgraduate diary column of the *Supplement* week by week.

## WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road W.—Daily, Medical Clinics, Surgical Clinics and Operations, Obstetrical and Gynaecological Clinics and Operations, Mon 2.30 p.m., Sir Edmund Spence, Diseases of Small and Large Intestine, Wed 12 noon, Clinical and Pathological Conference (Medical), 3 p.m., Clinical and Pathological Conference (Surgical), 4 p.m., Dr. C. H. Andr, Viruses, Thurs 2.15 p.m., Dr. Dunlop, Demonstration, 3.30 p.m., Mr. Victor Bonney, Malignant Neoplasms of Uterus, Fri 2 p.m., Clinical and Pathological Conference (Obstetrics and Gynaecology).

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1 Wimpole Street W.—*Maudsley Hospital*, Denmark Hill, S.E., Course in Psychological Medicine, *Infants Hospital*, Vincent Square S.W., Sat and Sun, Course in Children's Diseases.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn Road W.C.—Daily, Course in Anatomy and Physiology.

HOSPITAL FOR EPILEPSY AND PARALYSIS, Maida Vale W.—Thurs 3 p.m., Dr. Blake Pritchard, Clinical Demonstration.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street W.C.—Thurs 2 p.m., Mr. H. C. Apperley, The Milk Teeth, 3 p.m., Dr. Alan Moncrieff, Causes and Diagnosis of Enlarged Cervical Glands, Out-patient Clinics, mornings 10 a.m. to 12 noon, Ward Visits, afternoons 2 p.m. to 5.30 p.m.

INSTITUTE OF BRITISH SURGICAL TECHNICIANS—At Woburn Hotel, Welbeck Street W, Fri 8 p.m., Mr. W. H. Ogilvie, Uses of Instruments in Surgical Technique.

INSTITUTE OF PATHOLOGY AND RESEARCH, St. Mary's Hospital W.—Tues 5 p.m., Dr. Donald Hunter, Observations on the Toxic Action of Certain Compounds of Lead, Arsenic and Mercury.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westminster, S.W.—Tues 5.30 p.m., Dr. Paul Wood, Pericarditis.

ST. JOHN CLINIC AND INSTITUTE OF PHYSICAL MEDICINE, Royal Free, S.W.—Fri 4.0 p.m., Dr. G. T. Caldwell, Radiology in Physical Medicine.

MANCHESTER ROYAL INFIRMARY—Fri 4.15 p.m., Dr. W. J. Brockbar, Clinical Demonstration.

## DIARY OF SOCIETIES AND LECTURES

## ROYAL SOCIETY OF MEDICINE

Section of Otolaryngology—Mon 8 p.m., Paper by Mr. S. Wilson, Charles Developmental Movements of the Teeth, Clinical Communication by Mr. G. T. Hansen, Otitis Fibrosa—Lecture, Macleod's Simulating Osteogenic Sarcoma.

Section of Medicine—Tues 5 p.m. (Cases at 4 p.m.), Central Meeting, Middlesex Hospital, Cases will be shown.

Section of Epidemiology and Social Medicine—Wed 8.15 p.m., Paper by Dr. W. A. Duley, School Life and Afternoon of a Handicapped Child.

Section of Urology—Stockholm, Thurs and Fri, Annual General Meeting, Election of Officers and Council for 1955.

BRITISH PSYCHOLOGICAL SOCIETY, MEDICAL SECTION—At Tavistock Clinic, Mallet Place W.C.—Wed 5.0 p.m., Dr. H. G. Balfour, Psychological Demonstration of the Drawings of a Schizophrenic Artist.

CAMBRIDGE MEDICAL SOCIETY—At Adderbury, Hospital, Cambridge, Fri 5.30 p.m., Dr. J. D. Simpson, Corcoran.

CHELSEA CLINICAL SOCIETY—At Hotel Rembrandt, Trafalgar Place S.W.—Thurs 8.15 p.m., Dr. L. I. M. Castleden, Uses of Doses in Medicine, Preceded by dinner at 7.30 p.m.

MEDICO-LEGAL SOCIETY—At 16 Portland Place W.—Thurs 8.0 p.m., Mr. William Lacey, Medico-Legal Aspects of the Matrimonial Causes Act 1937.

ROYAL INSTITUTION, 21 Albermarle Street W.—Fri 9 p.m., Dr. R. N. Salaman, F.R.S., The Origin of the Pouch and its Influence on Man's Early Settlement in South America.

ST. JOHN'S HOSPITAL, DERMATOLOGICAL SOCIETY, L 10 St. John's W.C.—Wed 4.0 p.m., Clinical Cases, 5 p.m., Dr. J. H. T. Davies, Minor Surgery of the Skin with Special Reference to Boppy.

## VACANCIES

All advertisements should be addressed to the  
Advertisement Manager and NOT to the Editor.

## RESIDENT POSTS

ACCREDITED VICTORIA HOSPITAL—H.S. Salary £17 p.a.

ALTRINCHAM GENERAL HOSPITAL—(1) Senior H.S. £115 p.a. (2) Junior H.S. £100 p.a. and £110 p.a. respectively.

BANGOR, CERNARVONSHIRE AND ANGLESEY INFIRMARY—J.H.S. (male) Salary £10 p.a.

BARNLEY, BECKETT HOSPITAL AND DISPENSARY—CO (male) Salary £22.0 p.a.

BEDFORD COUNTY HOSPITAL—Second H.S. and CO (male) Salary £10 p.a.

BIRMINGHAM AND MIDLAND EYE HOSPITAL—H.S. Salary £10 p.a.

BIRMINGHAM CITY—MO (female) for Carwell Hall Baby Hospital in Maternity and Child Welfare Department, Salary £250 p.a.

BIRMINGHAM GENERAL HOSPITAL—(1) H.S. to Gynaecological Department, (2) H.S. to Throat and Ear Department, Salary £70 p.a. each.

BURTON, COSHAM MEMORIAL HOSPITAL, Loughborough—J.M.O. (male) Salary £100 p.a.

DEVONPORT, PRINCE OF WALES'S HOSPITAL—J.H.S. Salary £10 p.a.

DIDLEY GUEST HOSPITAL—(1) Surgical Officer, Salary £150 p.a. to £200 p.a. according to experience, (2) H.S. Salary £100 p.a. to £150 p.a. according to experience, (3) J.M.O. Salary £100 p.a.

DUNDEE MENTAL HOSPITAL, Westgate—J.A.M.O. (male) Salary £100 p.a.

ELING, KING EDWARD MEMORIAL HOSPITAL—H.S. (male) Salary £10 p.a.

EDINBURGH, ELSIE INGLIS MEMORIAL MATERNITY HOSPITAL—Assistant Obstetric Registrar (female), Salary £100 p.a.

HALIFAX, ROYAL HALIFAX INFIRMARY—Second H.S. (male) married, Salary £175 p.a.

HARTLEPOOL HOSPITAL—H.S. Salary £10 p.a.

HASTINGS, ROYAL EAST SUSSEX HOSPITAL—J.H.S. (male) Salary £10 p.a.

HENLEY HEMPSTEAD, WEST HERTS HOSPITAL—J.M.O. (male) Salary £100 p.a.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.—(1) Assistant P. (2) Two Medical Assistants and Clinical Pathologist.

logists (3) Assistant Surgical Officer (4) H.S. Unmarried Salaries £200 p.a. £125 p.a. £100 p.a. and £50 p.a. respectively

HUDDERSFIELD ROYAL INFIRMARY—(1) H.S. (2) H.S. for Abnormal Maternity Department (3) H.S. for Eye Ear Nose and Throat Departments Males Salaries £150 p.a. each

LEEDS KING GEORGE HOSPITAL—Assistant C.O. and H.S. (male) to Special Departments Salary £100 p.a.

LIVERPOOL STIRLING DISTRICT MENTAL HOSPITAL—J.A.M.O. (male) Salary £300 p.a.

LEEDS GENERAL INFIRMARY—(1) Ophthalmic Officer (2) Aural Officer Salaries £149 p.a. each

LICHFIELD CITY—M.O. (male) for City General Hospital Salary £300 p.a.

LONDON COUNTY COUNCIL—A.M.O.s (Grade II) for (a) Princess Mary's Convalescent Home Cliftonville Margate (b) St. Alge's Hospital Vinburgh Hill Greenwich S.E. (c) St. Francis Hospital East Dulwich S.E. (d) St. George in the East Hospital, Raine Street Wapping E. and (e) St. Luke's Hospital Sydney Street S.W. (a) is a female appointment only Unmarried Salaries £250 p.a. each

LONDON LOCK HOSPITAL Harrow Road W.—M.O. (male) Salary £175 p.a.

LOWESTOFT AND NORTH SUFFOLK HOSPITAL—J.H.S. (male) Salary £120 p.a.

MANCHESTER CITY—A.M.O. for Withington Hospital Salary £200 p.a.

MIDDLESEX COUNTY COUNCIL—Whole time Casualty M.O. for West Middlesex County Hospital Isleworth Salary £350 p.a.

NEWBURY ROYAL GWENT HOSPITAL—(1) H.S. to Fracture and Orthopaedic Department (2) C.O. Salaries £135 p.a. each

NORTHAMPTON MANFIELD ORTHOPAEDIC HOSPITAL—M.O. (male) Salary £200 p.a.

NORTHWOOD MOUNT VERNON HOSPITAL—H.S. Salary £150 p.a.

NOTTINGHAM CITY—Assistant Surgical Officers for City Hospital Salaries £250 p.a. each

NOTTINGHAM GENERAL HOSPITAL—C.O. (male) Salary £150 p.a.

OXFORD WINGFIELD MORRIS ORTHOPAEDIC HOSPITAL Headington H.S. (male) Salary £100 £120 p.a. according to experience

PADDINGTON GREEN CHILDREN'S HOSPITAL (INC.) W.—H.S. (male, unmarried) Salary £150 p.a.

PRISTON ROYAL INFIRMARY—C.O. Salary £150 p.a.

ROCHDALE INFIRMARY AND DISPENSARY—Second H.S. (male) Salary £150 p.a.

ROTHERHAM HOSPITAL—H.P. (male) Salary £180 p.a.

ROYAL FREE HOSPITAL Gray's Inn Road W.C.—Senior M.O. (male) Salary £150 p.a.

RUEBY HOSPITAL OF ST. CROSS—M.O. (male) Salary £100 £150 p.a.

SALISBURY GENERAL INFIRMARY—H.P. (male, unmarried) Salary £125 p.a.

SHEFFIELD CITY—A.M.O. (Grade I) (male) for City General Hospital Salary £350 £25 £450 p.a.

SHROPSHIRE GENERAL INFIRMARY—Senior H.S. Salary £175 p.a.

ST. ALGE'S INFIRMARY—H.S. (male, unmarried) Salary £150 p.a.

STOKES TRENT NORTH STAFFORDSHIRE ROYAL INFIRMARY—Anaesthetist Salary £150 p.a.

STOKES TRENT CITY—M.O. (male unmarried) for Stinfield Sinatonium Salary £250 p.a.

STROUD GENERAL HOSPITAL—M.O. Salary £160 p.a.

SUNDERLAND ROYAL INFIRMARY—J.H.S. (male) Salary £120 p.a.

SWANLEY HOSPITAL CONVALESCENT HOME Parkwood—M.O. (female) Salary £200 p.a.

WEIR HOSPITAL Grove Road Bilham S.W.—J.M.O. (male, unmarried) Salary £150 p.a.

WORCESTER ROYAL INFIRMARY—J.H.S. Salary £120 p.a.

### NON RESIDENT POSTS

FAIRBOURNE PRINCESS ALICE HOSPITAL—Hon. Assistant Radio logist

MAIDENHEAD HOSPITAL—Hon. S. for Ear Nose and Throat Department

MANCHESTER ROYAL INFIRMARY—Chief Assistant to a Surgical Unit Salary £250 p.a.

OXFORD RADCLIFFE INFIRMARY—Surgical Registrar Salary £400 p.a.

SOUTH EASTERN HOSPITAL FOR CHILDREN Sydenham S.E.—Hon. Assistant S.

### UNCLASSIFIED

BIRMINGHAM CITY—M.O. (female) for Maternity and Child Welfare Department Salary £200 £25 £700 p.a.

BIRMINGHAM CITY AND COUNTY—Two Whole time Assistant M.O.s (one male and one female) Salaries £200 £50 £700 p.a. each

LEEDS KING EDWARD MEMORIAL HOSPITAL—(1) Consulting Physician (2) Second Consulting Laryngologist

GLoucester CORPORATION—Assistant M.O.H. (male) Salary £500 p.a.

HULL ROYAL INFIRMARY—Assistant M.O.H. and Assistant School M.O. Salaries £200 £25 £750 p.a.

LEEDS AND LEICESTER COUNTY COUNCIL—Assistant M.O.H. (male) Salary £200 p.a.

LEEDS AND LEICESTER COUNTY BOROUGH—Assistant M.O.H. (female) Salary £200 p.a.

LEEDS AND LEICESTER COUNTY DISTRICT GENERAL HOSPITAL—Part time M.O. Salary £200 p.a.

LEEDS AND LEICESTER COUNTY DISTRICT GENERAL HOSPITAL—(1) Part time Surgical Registrar (2) Part time Medical Registrar Males Honorariums £225 p.a. and £175 p.a. respectively

LONDON CORPORATION Guildhall, E.C.—M.O.H. for Port of London Salary £1 500 £2 000 p.a.

LONDON COUNTY COUNCIL—A.M.O.s for mental health services Salaries £470 £25 £570 p.a. each (Female applicants to be unmarried)

MANCHESTER ROYAL EYE HOSPITAL—Out patient M.O. Salary £200 p.a.

MANCHESTER ROYAL INFIRMARY—Director of Clinical Laboratory Salary £800 p.a.

MIDDLESEX COUNTY COUNCIL—(1) Whole time Assistant District Officer (male) Salary £500 £25 £700 p.a. (2) Visiting Dermatologist for Redhill County Hospital, Edgware Pcc £3 15 p.a. session

MIDDLESEX HOSPITAL W.—Obstetric and Gynaecological Registrar Salary £300 p.a.

NEWCASTLE-UPON-TYNE ROYAL VICTORIA INFIRMARY—Whole time Registrar to Orthopaedic Department Salary £150 p.a.

NEWCASTLE-UPON-TYNE UNIVERSITY OF DURHAM AND ROYAL VICTORIA INFIRMARY—Professorship of Pathology, tenable at King's College, Newcastle upon Tyne, and Pathologist to Royal Victoria Infirmary Newcastle Salary £1 100

PADDINGTON GREEN CHILDREN'S HOSPITAL (INC.) W.—Two Clinical Assistants to Medical Out patients

QUEEN MARY'S HOSPITAL FOR THE EAST END Stratford, E.—Hon. Assistant S. with charge of out patients

ROYAL LONDON OPHTHALMIC HOSPITAL City Road, L.C.—Out patient officer Salary £100 p.a.

ST. BARTHOLOMEW'S HOSPITAL E.C.—Part time Chief Assistant for X-ray Diagnostic Department

STOKES TRENT CITY—Whole time M.O. (male) of Venereal Diseases Centre Salary £750 £937 10s p.a.

WAKEFIELD WEST RIDING OF YORKSHIRE MENTAL HOSPITALS BOARD—A.M.O. for Wakefield Mental Hospital Salary £150 £25 £450 p.a.

WIMBOROUGH—(1) Whole time Assistant M.O.H. Salary £500 £25 £700 p.a. (2) Part time Assistant M.O. Remuneration £1 11s 6d per session

WEST LONDON HOSPITAL Hammersmith Road W.—Chief Assistant to Department for Chronic Rheumatic Diseases Honorarium £100 p.a.

CERTIFYING FACTORY SURGEONS—The following vacant appointments are announced Llandrindod Wells (Radnorshire) Billingham (Lincolnshire) Haddenham (Cambridgeshire) West Calder (Midlothian) Applications to the Chief Inspector of Factories Home Office, Whitehall, S.W.1, by April 26

To ensure notice in this column advertisements must be received not later than the first post on Tuesday mornings

Notifications of offices vacant in universities medical colleges and of vacant resident and other appointments at hospitals will be found at pages 57 58 59 60 61 64 and 65 of our advertisement columns and advertisements as to partnerships assistantships and locumtenencies at pages 62 and 63

### APPOINTMENTS

MACKEITH S.A., MRCS L.R.C.P., D.P.M. Honorary Consulting Physician in Charge of the Department of Psychological Medicine, Warneford General Hospital Leamington Spa

CERTIFYING FACTORY SURGEONS—A.S. Beer M.B. F.R.C.S.L.D. for the Thame District (Oxfordshire), G.S. Christie M.B. Ch.B. for the Fordoun District (Kincardine), J.C. Christie M.B. D.P.H. for the Perth District (Perthshire), J.H. Christie M.B. B.Ch. for the Abingdon District (Berkshire), J.P. Christie L.R.C.P. and S. for the Kelvedon District (Essex), W.F. Christie M.R.C.S. L.R.C.P. for the Reynoldsford District (Gloucestershire), J.T. Murphy, M.B., B.Ch., for the Culston District (Devonshire)

LONDON COUNTY COUNCIL—The following appointments have been made at the hospitals indicated in parentheses Deputy Medical Superintendent Grade I J. Jemson, F.R.C.S. (St. Alge's) Deputy Medical Superintendent Grade II A.N. Jones, F.R.C.S. (St. Pancras) Assistant Medical Officers Grade I C.W.C. Karran M.B. (Park) A.B. Christie M.B. Ch.B. D.P.H. (Eastern) H.W. Hall M.B., Ch.B., D.P.H. (Brixton) H.L. Settle M.B. Ch.B. (Grove)

### BIRTHS, MARRIAGES, AND DEATHS

The charge for insertion, announcements of Births Marriages and Deaths is 9s which sum should be forwarded with the notice not later than the first post on Tuesday morning in order to ensure insertion in the current issue

#### BIRTH

BENTON—On April 11 at City Hospital Nottingham Dr. Sidney B. Benton a daughter

#### MARRIAGE

WARRIN—Bruce—April 12 at Bingley John Fairbairn M.B. Ch.B. D.P.H. Leeds of Tadcaster to Kathleen S. Warrin M.B. Ch.B. D.P.H. Leeds of Bingley at Ryddington 271 Preston New Road Bingley

# EPITOME OF CURRENT MEDICAL LITERATURE

## Medicine

### 330 Agranulocytosis due to Pyramidon

A GUES (*These Paris* 1937, No 793) who records three illustrative cases in women aged 27, 29 and 30 respectively states that though pyramidon may give rise to agranulocytosis this sequel is relatively rare especially in France, where considerable use is made of the drug. The clinical picture so produced in no way differs from agranulocytosis due to other causes. The prognosis however is less severe than in the primary form. Of 128 cases of agranulocytosis due to pyramidon collected by Plum seventy or 54 per cent., were fatal, while among thirty three cases of primary agranulocytosis reviewed by Gues there were twenty deaths—a mortality of 60 per cent. The pathogenesis is still obscure. The sequel appears to occur only in special subjects who for some unknown reason are particularly sensitive to pyramidon, and may be regarded as a sort of anaphylactic reaction. Prolonged administration of large doses of pyramidon should therefore be avoided when a predisposition to anaphylaxis may be suspected.

### 331 Pulmonary Stenosis

C LIAN and J-J WELTI (*Arch Mal Cœur* December 1937, p 946) describe an auscultatory phenomenon which they say may be observed in about 10 per cent of cases of congenital pulmonary stenosis. It consists of a short, clear clapping sound at the beginning of systole. This is superimposed on the second half of the first sound which is thus reduplicated. The maximum intensity of this sound is at the inner end of the second and third left intercostal spaces. It is sometimes possible to palpate a vibration corresponding to this sound. The sound is not widely propagated, and is lessened or abolished by inspiration. It may sometimes appear as a marked intensification of the first sound in the pulmonary area since the ear cannot clearly distinguish the dull initial part of the first sound preceding the clapping sound. It is suggested that the phenomenon is due to the increased tension of the dome formed by the adherent segments of the pulmonary valve in the early part of systole. It has also been heard in cases of pulmonary arteritis in which condition it may be due to increased tension of the diseased walls of the artery. Six cases are described in which this sound was an important sign. Electrocardiograms show that the clapping sound coincides with the latter half of the first sound and precedes immediately the systolic bruit from which it is not separated by any interval of silence.

### 332 Tuberculosis in Medical Students

J HOLM and P HELWEG LARSEN (*Ugeskr Laeg* February 3 1938 p 116) give an account of a three year study of medical students in Denmark which began in the spring of 1934. The examination which was ostensibly voluntary but in practice more or less obligatory began with Mantoux's intracutaneous tuberculin test, repeated when necessary till a dose of 1 mg of international standard tuberculin was attained. The negative reactors were not for the moment further examined whereas the positive reactors were radiologically examined. The Mantoux testings were so spaced that the student would have to submit to them six times during the six and a half years of the curriculum. Of the 1608 students examined 1,192 were found from the outset to be positive reactors. The proportion of positive reactors rose from 69 per cent among junior students to 95 per cent among the most senior students. In the 1,192 originally positive reactors were twelve students who already knew that they had contracted pulmonary tuberculosis. Among the remaining 1180 there were

1161 with radiologically normal lungs. There were nineteen who seemed to be perfectly well but whose lungs showed radiological evidence of tuberculosis. Of the 1161 Mantoux positive students with radiologically normal lungs twenty had a history of tuberculosis of the pleura, knee, peritoneum etc. During the three year observation period none of the 1161 Mantoux positive students with radiologically normal lungs developed pulmonary tuberculosis whereas among the 416 originally Mantoux negative students there were as many as nineteen who had evidence of pulmonary tuberculosis after Mantoux's reaction had become positive. Twenty seven original Mantoux negative students were given intracutaneous injections of BCG which rendered them Mantoux positive; none of them developed pulmonary tuberculosis. The authors conclude that the student most likely to contract pulmonary tuberculosis during the medical curriculum is the originally negative tuberculin reactor.

### 333 Ascorbic Acid and Gelatin

G IZAR and G CAZZONE (*Riv med* January 8 1938 p 5) state that systematic investigations carried out at the medical clinic at Messina University have shown that subcutaneous injections and the administration by mouth of laevo ascorbic acid cause a fall in the blood sugar in both normal and diabetic subjects this fall reaching its maximum about an hour after the injection of vitamin C and being followed by a progressive rise up to the original level in the next three hours or so. Further investigations proved that gelatin in a 2 per cent sterile solution and glycerin in a 40 per cent sterile solution added to equal quantities of a solution of ascorbic acid considerably increased this hypoglycaemic action and made it persist for a longer period.

## Surgery

### 334 Haematemesis of Splenic Origin

G CHIORAZZO (*Riv med* January 15 1938 p 46) states that patients with chronic splenomegaly are relatively often liable to severe haemorrhages which are usually manifested by haematemesis owing to the high position of the bleeding point in the alimentary tract. The splenic tumour is of a congestive or fibro-congestive type either secondary to a mechanical obstruction to the discharge of blood into the spleen (thrombophlebitis occlusa or compression of the splenic vein) or primary and independent of any changes in the portal circulation. There are two characteristic features—namely the severity of the haemorrhage and the suddenness of its appearance. The patients are usually young persons who have been suffering for some time even years from anaemia and loss of flesh vague pains in the left hypochondrium frequent dyspepsia and not uncommonly irregular fever. On examination a large hard mass is found in the left half of the abdomen suggesting a splenic tumour. Treatment can only be surgical and consists in either splenectomy or ligation of the splenic artery which the author prefers as being a less severe operation.

### 335 Direct Extension for Spinal Injuries

R SÆLER (*J Chir Brux* December 1937 p 661) discusses the treatment of dislocation and fracture of the cervical vertebrae and suggests a method of treatment which was tried in two cases both well reported. It consists in the direct application of traction through the skull. Two different methods are described in which traction is applied through a steel wire inserted into open trephined in the parietal bone on either side. In the

second method traction is made by means of a stirrup devised by Schmerz this procedure is simpler and safer, it was also found that it caused less discomfort to the patient than any other method of treatment. In one case extension by this means was carried out for nearly a month without any inconvenience after the first few days. Direct traction is recommended even in the presence of a fracture of the lower jaw a lesion which is often associated with cervical injuries. By this means reduction is quickly brought about a factor which is of importance in cases of medullary compression. The patient can be moved without the extension being interfered with. This method of treatment is contraindicated when a wound is present in the parietal region or when there is infection of the scalp. It is suggested that direct traction might also be of value in other lesions of the spinal column, such as osteomyelitis or Pott's disease.

### 336 Surgical Treatment of Acute Mastitis

J. KREIS (*Gynec. et Obstet.* December, 1937, p. 499) emphasizes the unsatisfactory results of the surgical treatment of acute mastitis by means of large radial incisions. Convalescence is long the wound heals by granulation, and the cosmetic result leaves much to be desired. Acute mastitis is often seen with multiple abscesses in different stages of development. A method of treatment which has proved successful is by means of a para-areolar circular incision round the edge of the pigmented area of the areola. The incision is made through the skin until pus is reached. The cavity is then enlarged by inserting a pair of forceps, and these are opened as they are withdrawn and a rubber drain is inserted. The abscess forms a triangle the apex of which is beneath the nipple. If the abscess lies towards either the axilla or the sternum the incision is made on the side affected. Sometimes an incision on both sides is necessary. In the lower half of the breast a para-areolar incision is made with a counter-incision below for drainage. This counter-incision must always be in the breast itself and must follow the contour of the breast. Drainage is by means of perforated rubber tubing and should be of as short a duration as possible. Forty-three cases have been treated by this method with good results.

## Therapeutics

337

### Agranulocytosis

L. BAUMANN (*Munch. med. Wschr.* February 11, 1938, p. 204) agrees with other workers that in the treatment of agranulocytosis few successes have followed the injection of nuclein preparations, liver extracts, turpentine, leucocyte suspensions or yellow marrow or treatment with x-rays. He states that transfusions of normal blood have never been effective but alludes to the very recent reports of Bok and of Deglinn of cures effected by the transfusion of blood from a patient suffering from myeloid leukemia. He reports a severe case of agranulocytosis, in a woman aged 59 who does not appear to have taken pyrimidon treated by two months intramuscular injections of increasing doses of an extract of calves red marrow. Clinical and hematological cure followed in spite of the initial gravity of the condition, as shown in spinal puncture by the absence of myeloblasts, promyelocytes or other neutrophil cells and by the negative oxidase reaction of the other cells present. The extract was equally effective after being made protein-free. A temporary improvement had occurred at an earlier stage at the daily oral administration of 150 to 200 grammes of calves red marrow. The success of injections of red marrow or of myeloid leukemic blood suggests that red marrow contains an anti-leucoplastic principle perhaps similar to the anti-anæmic principle of Castle,

if this is so, then it seems possible that leukemia may be regarded as a condition of hormonal origin.

338

### Polycythaemia Vera

M. R. MCALPINE and K. E. SMITH (*N.Y. State J. Med.* January 15, 1938, p. 101) report upon fourteen cases of polycythaemia vera treated with acetylphenylhydrazine. These cases are compared with a series of ten cases treated by them with phenylhydrazine and reported two years ago. The severity of the polycythaemia varies considerably, the highest red cell count being 11,700,000. Six patients were Jews, one was a Greek, and one an Armenian, two were plumbers and two painters. Three patients had peptic ulcers. The treatment given was 0.1 gramme of acetylphenylhydrazine for two or three days in the course of a week. This was repeated for several weeks and then the dose was increased gradually to 0.4 or 0.5 gramme. In only one case did jaundice occur, in two other cases there was a susceptibility to the drug. The results of treatment, which was controlled by weekly blood counts, showed that nine patients were improved, two did not improve, and three died. At the two necropsies performed no signs of poisoning were found. Two of the fatal cases showed also Ayer's disc. In the opinion of the authors acetylphenylhydrazine is superior to phenylhydrazine hydrochloride in the treatment of polycythaemia vera.

## Radiology

339

### Radiotherapy of Hemiplegia

P. LE GOLF (*J. Radiol. Électrol.* December, 1937, p. 511) recommends radiotherapy for the treatment of the sequelae of hemiplegia. X-rays have a beneficial effect not only on the primary lesion but also on the associated symptoms. The whole of the affected hemisphere is irradiated, the focal distance being not less than 40 cm. and the initial doses not more than 5 to 20 r at 120 to 150 kV, filtered through 0.3 to 0.5 mm. of copper. The dose is gradually increased to 100 r at each sitting. To eight treatments are given in each series of treatment, the series being repeated at gradually increasing intervals. There are no contraindications to the treatment which should be begun as soon as possible. The author reports a number of personal observations on a series of cases treated. In some of the cases reported the results are remarkably good.

340

### Fate of Thorium Dioxide

W. FREEMAN (*Arch. Neurol. Psychiat.* Chicago 1937) describes the effects of intraventricular injections of thorium dioxide on the ventricles and the subarachnoid space. His material was obtained from two biopsies, eight necropsies, and the time interval after injection varied from one hour to two months. As to the ventriculography thorium dioxide is a buffered colloidal solution stabilized by a protective colloid consisting of a solution of dextrin. If injected into a closed cavity protective colloid is dispersed and the thorium dioxide flocculates, forming plaques on the walls which remain for an indefinite period, but if the ventricular system is unobstructed the colloidal suspension is eliminated. In the choroid plexus an exudative inflammation is produced which is maximal twenty-four hours after injection and clears up within four days. It causes oedema, marked leucocytic infiltration and separation of the epithelium. A transitory inflammatory reaction is also produced in the ependyma and the meninges in non-obstructive cases. In the latter there is no plastic inflammation and no tendency for the meninges with blocking of the cerebrospinal pathways. In a case of obstructive hydrocephalus

was found, however four days after the injection extensive alteration in the ependyma and widespread exfoliation of the ependymal lining with masses of cellular exudate in which were leucocytes macrophages and a few lymphocytes mingled with both free and intracellular particles of thorium dioxide. Numerous minute focal haemorrhages were also present. In another case after two months the ependyma was not regenerated but in its place there was a bare fibrous glial lining with a thin sheet of histiocytes containing particles of thorium and occasionally histiocytic aggregates of larger size. Free man concludes that the possibility of a progressive inflammation with the formation of a granulomatous lesion is precluded by the inertness of thorium. The possibility of a late effect on the brain from the standpoint of radioactivity is also considered to be slight because normal cerebral tissue is not susceptible to radiant energy and the small quantities injected rapidly disappear. The ultimate fate of the thorium and its effects on the tissues in general are questions for future decision.

### 341 Genito-urinary Carcinomata

W TESCHENDORF (*Z Urol* 1938, 38 1 11) agrees with the majority of urologists that all operable urological conditions should be treated by operation even if they are amenable to x-ray therapy. He discusses the radiotherapeutic method of Seitz and Wintz, which on the whole proved disappointing in new growths of the urinary organs. The results greatly improved however after the introduction of the method of fractional dosage of which the author gives a brief outline. He describes in detail the application of the method slightly modified by himself in cancer of the kidneys and bladder. By this technique it was possible to apply to the tumour itself 3,200 to 4,000 r units within about three weeks and in weak patients within about four to five weeks. The author gives a statistical survey of the results of radiotherapy in cancer of the bladder prostate kidneys urethra and penis in a fair proportion of cases the treatment resulted in cure or in a long remission. He concludes by stressing the importance of close collaboration between the urologist and radiotherapist.

### 342 Visualizing the Left Auricle

B ENQUIN and J A AGUIRRE (*Rev argent Cardiol* September-October 1937 p 227) state that antero-posterior radiographs of patients with mitral stenosis taken from a short distance (90 cm) with hard rays and exposure times of from 1/10 to 3/10 second using a Potter-Bucky apparatus give a good view of the left auricle in some cases the auricle was only slightly dilated. Its shadow was clearly recognized in cases of pure mitral insufficiency. Two radiographs showed a triple contoured concentric shadow the third arch was determined by a spindle shaped shadow within the auricular image and was shown to be due to displacement of the oesophagus to the right.

### 343 Irradiation of Sympathetic Ganglia for Arthritis

DUHEM MORO and MONTMIGNAUT (*Presse med* January 29 1938 p 153) have treated a series of twenty five cases of arthritis of the hip joint by x rays applied to the second lumbar sympathetic ganglion. The skin landmark for this ganglion corresponds to a point situated 3 cm to the side of the spinous process of the second lumbar vertebra. Where the affection is unilateral the central ray is made to strike this point. The point of entry is 10 cm by 10 cm so that the first and second lumbar vertebrae are irradiated at the same time. It is immaterial whether the central ray is vertical to the frontal plane of the spine or inclined at 20 degrees towards the sagittal plane. In cases of bilateral arthritis the central ray is made to strike the spinous process of the second lumbar vertebra. Hard radiation of 180 to 200 kV is used,

filtered through 0.5 mm of copper and 2 mm of aluminium. The total distance is 40 cm. 120 r units are given at each sitting twice weekly for three weeks (total of 900 r units). In four of the twenty five cases treated an improvement was noticed after two to three treatments in six cases after four treatments in eight cases after six treatments and the remaining cases responded only fifteen days after the end of the course of treatment. It is yet too early to say whether the improvement will be lasting but in view of the relatively small doses the treatment could be repeated several times.

### 344 General Effects of X-Ray Therapy

P BLUMEL (*Beitr klin Chr* 1938 167, 7 1) has been able to prove by experiments on animals that small doses of x rays seem to immunize the body against the spread of a carcinoma while large doses accelerate the invasion. This is probably due to the fact that irradiation releases certain specific products which immunize in small doses but are toxic in large doses. The conclusions from animal experiments are not directly applicable to man. The reaction to irradiation in healthy animals subsequently inoculated with tumour cells must be different from the reaction to irradiation in a cancerous human patient. Certain general principles however are common to both. The immunizing effects of irradiation are of secondary importance in the treatment of radio sensitive growths. In such cases it is only of importance to avoid as much as possible a decrease of the patient's resistance to the growth. This can be achieved by the avoidance of large fields by tangential application of the rays by fractional dosage and similar measures. In tumours which are radio resistant the treatment should aim only at increasing the general resistance to invasion. This can be achieved in a number of ways—for example by prophylactic irradiation after operation for a carcinoma of the breast. Recently the author has tried the effect of small doses of x rays in cases of gastric carcinomata. By a judicious distribution of the doses it was possible to administer a fairly large total dose to the tumour itself the results so far have proved encouraging. The author's experiments have also confirmed the importance of general treatment of carcinomatous patients, the patient's resistance should be increased by all available means.

### 345 X-Ray Therapy of Enlarged Tonsils and Adenoids

P GIBERT (*J Radiol Electrol* January 1938 p 19) advocates x-ray therapy for enlarged tonsils and adenoids in children. He uses a moderately penetrating radiation filtered through 10 mm of aluminium or 0.5 mm of copper. The skin focus distance is 23 or 25 cm with large ports of entry extending from the zygomatic arch to the clavicle. He gives two bilateral applications of 160 r units to each field—rarely three or four applications—within two to three weeks. The lymphoid tissue is very radio sensitive and at the same time the x rays have a beneficial effect on the inflammatory condition. The method is particularly advisable in the very young where operation is feared because of possible complications. The treatment is harmless thanks to the small doses used and does not interfere with a subsequent surgical operation in cases where x-ray therapy fails. On the other hand x rays may effect a cure in cases of recurrence after operation.

### 346 Total Teleradiotherapy for Blood Diseases

G MARCHAL, L MALLET and A BELLIN (*Paris med* February 5 1938 p 113) report the results of total teleradiotherapy in the leukaemias in Hodgkin's disease and in polycythemia. According to the condition of the blood they used a skin focus distance of either 2.4 metres—mainly in Hodgkin's disease and in polycythemia—in which the red blood corpuscles are fairly resistant—or 2 metres in cases predisposed to anaemia—for example

in monocytic leukaemia. The doses were very small, usually 5 to 10 *r* units at each treatment, gradually increasing up to not more than 30 *r* units. Treatments were given twice weekly for two to ten weeks according to the reaction of the patient; the interval between each series of treatments also varied according to the patient's reaction. In two out of seven cases of chronic monocytic leukaemia the results of the treatment were brilliant, in the remaining five indifferent or transitory. A case of lymphoid leukaemia was favourably influenced and the patient was kept comfortable for four years. The results in five cases of myeloid leukaemia were on the whole satisfactory, sometimes exceptionally good. Of twenty-four cases of verified lymphogranulomatosis excellent results were obtained in more than half, in some of the cases however it was necessary to treat the large swellings with local irradiation. In two cases of polycythaemia the results were very satisfactory, amounting practically to a clinical cure.

### 347 Broncho-pulmonary Radiating Shadows

R. D'AMBROSIO and M. FERRARA (*Lotta c. Tuberc.*, October 1937, p. 935) discuss the radiological diagnosis of the pre-phthisical state (as described by Bezançon and Braun-Sergent and others) in which a latent pulmonary tuberculosis is characterized by (1) vague depreciation of general health, (2) indefinite pulmonary signs and symptoms including cough, bronchitis, asthma, dry pleurisy and slight haemoptysis, and (3) radiological signs which are not localized but consist chiefly in a diffuse accentuation of the normal broncho-pulmonary shadows and in the presence near the chest wall of abnormal linear prolongation of these shadows. In such a condition the pleuro-pulmonary vascular connective tissue network is said to be the site of latent discrete, "closed" tuberculous lesions, their spread being either centripetal or centrifugal along the rich network of accompanying lymphatics. A later result is a subpleural, peribulbar, and peribronchial formation of bands of sclerosis. The condition has been termed 'tramitis'. D'Ambrosio and Ferrara, in repeated examinations of 500 sanatorium patients including early and late cases, found only twelve in which satisfactory evidence of tramitis was present; they emphasize the importance of taking several radiographs at intervals. Evolution towards cure, fibrosis, or excision and cavitation was noted in different cases.

## Obstetrics and Gynaecology

### 348 Vaginal Stenosis

G. TSOLLOPOULOS and J. PLATZ (*Zbl. Gynak.*, February 5, 1938, p. 290) allude to special forms of vaginal stenosis, thought to be due to ovarian insufficiency which have been recently reported in the German literature. Novak, in 1925 and again in 1936, and Labhardt, independently in 1936, described a circular contraction just below the cervix at the level at which the border of the levator ani crosses the vaginal wall. This stenosis called by Labhardt *krampfsartige Vaginismus*, is not readily dilatable mechanically, causes severe dyspareunia, is accompanied by leucorrhoea and lower abdominal discomfort and though commoner about or after the climacteric is also seen in younger women and may cause dystocia. Halban, in 1937, described a similar condition in women aged from 42 to 52, the ring-shaped contraction, however, is found at the base of the hymen and was named *cirrhosis annularis subhymenalis*. The first condition was described as being due to ovarian hypofunction and by Labhardt as reacting to treatment by follicular hormone. The present authors record an example of the second condition, and also observed an excellent response to protracted treatment with large doses. They therefore consider it especially in young subjects (their patient was

a sterile woman aged 34), that this treatment should precede surgical intervention (splitting or, better, excision of the ring of contracted connective tissue) such as was recommended and successfully employed by Halban.

### 349

#### Eclampsia

R. T. MEURER JUN (*Nederl. Tijdschr. Geneesk.*, February 13, 1938, p. 736) states that the incidence of eclampsia at the Amsterdam Obstetrical College during the period 1900 to 1937 has declined from 1 in 423 to 1 in 1,073 pregnancies, chiefly as the result of the prophylactic measures taken, and especially the improved antenatal care. He maintains that the general adoption of these measures throughout the country would reduce the frequency of eclampsia to under 1 per 1,000. The risk of eclampsia is much greater in primiparae than in multiparae.

## Pathology

### 350 Errors of Interpretation of Sedimentation Rates

P. BLICKMANN (*Dtsch. med. Wschr.*, January 14, 1938, p. 83) has studied 515 patients who came under a national tuberculosis scheme. Common to all these cases were their afebrile course and the clinical improvement noted during the first four to six weeks of treatment. Among the 296 male patients were eighty-five whose sedimentation rates were higher than they had been four weeks earlier in spite of clinical improvement. Among the 219 female patients, fifty-eight presented the same phenomenon. Thus, in 27 per cent of the 515 patients the evidence of the sedimentation rate was at variance with the clinical evidence. The author believes that the sedimentation rate may be changed by many different factors such as drugs, baths, massage, radiological treatment, and diet. There are also certain sources of error in the technique of the test after the blood has been withdrawn. In a group of seventy-one cases in which most, if not all, such disturbing factors were eliminated he found only four cases in which a rise of the sedimentation rate could not be accounted for by the clinical evidence. It is thus possible to reduce the misleading findings from 27 to 6 per cent. With regard to errors in the technique of the test, he advises puncture of the skin only after it has been thoroughly dried so that the needle does not pass through any ether or alcohol, otherwise the disinfectant introduced into the sample of blood examined may affect the sedimentation rate. Another important point is to keep the sample of blood examined at a uniform temperature of 20° C.

### 351

#### Hyperadrenalism and Buerger's Disease

N. MAGGI and L. PARODI (*Arch. ital. Chir.*, 1937, 47, 5481) recall that a hyperadrenalism was suggested by Oppel in 1921 as a possible cause of Buerger's disease, and that favourable if transitory effects have followed excision of the suprarenal medulla or the suprarenal on one side. Maggi has previously reported that repeated subcutaneous implantations into guinea-pigs of suprarenal tissue causes hyperplasia and degeneration of the media in the small arteries together with intense intimal proliferation and desquamation; in the veins there are somewhat similar changes not infrequently going on to obstruction of the lumen. From the observation that such changes were less easily induced by implants in females than males he was led to test the effect of preliminary castration on the experimental arterial changes in male guinea-pigs. Castration alone had no effect, but if the castration was followed by implants of guinea-pigs' ovary the arterial changes following the suprarenal implantations were insignificant and venous alterations absent. This finding is regarded as confirming the value of therapeutic trial in Buerger's disease, of injection of ovarian extracts.

At the request of their Medical and Nursing friends Cow & Gate have introduced a new and improved Glucose

Glucose A D is pure medicinal Dextrose with calcium glycerophosphate. It is entirely free from artificial vitamins the Vitamins A and D being derived from a natural source.

Glucose is particularly indicated in the vomiting and bilious sickness of children, acidosis, malnutrition and debility. Owing to its rapid assimilation the energy and nourishment provided in Glucose A D are immediately available.

Clinical samples and literature will gladly be sent on to any member of the Medical and Nursing Professions.

## A·D

# MILTON

Detergent, Penetrative, GERMICIDAL, Osmotic, Non-toxic,  
Liquefactive, Regenerative

**GERMICIDAL** Milton acts lethally on all the common pathogenic organisms found in wounds and infected areas generally, with a Hygienic Laboratory coefficient for *B typhosus* of 4.98

Other typical coefficients are —

<i>B. Coli communis</i>	2.12
<i>B. tetani</i>	1.34
<i>B. anthracis</i> (spores)	2.66
<i>B. enteritidis</i>	2.12
<i>B. influenzae</i> (Pfeiffer)	2.65
<i>B. tuberculosis</i>	2.17

The qualities of this carefully designed preparation and its superiority over other "hypochlorite" antiseptics—e.g., Dakin's Fluid and Liq. sod. chlorinatæ—have been clearly demonstrated by special laboratory researches, the results of which have been amply confirmed in practical use. Reports of these researches and a sample of Milton will be forwarded to any medical practitioner on request.

Milton is supplied at a standard strength ready for immediate use, and is stable. It is safe for either external or internal application.

MILTON PROPRIETARY LIMITED, JOHN MILTON HOUSE, LONDON, N 7

Announcing

# PERTUSSIS ANTIGEN (DETOXIFIED)

*Lederle*

THIS new form of therapy is recommended for the treatment of active cases of Whooping Cough as well as in general prophylaxis.

Free from bacterial cell, PERTUSSIS ANTIGEN (DETOXIFIED) *Lederle* is a departure from the usual form of vaccine therapy. Based upon a toxic principle derived from *H. pertussis*, treatment with formalin converts the toxic factor into a non-toxic substance having antigenic properties.

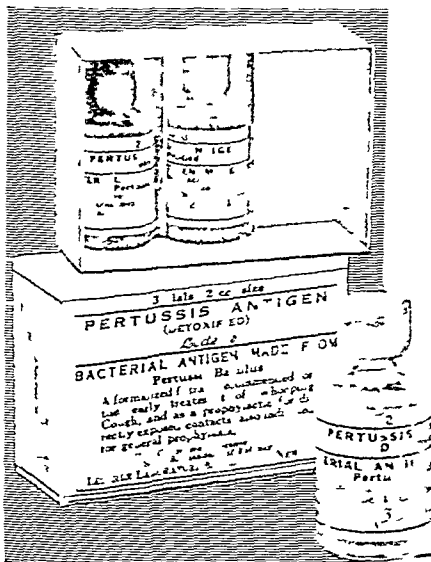

It used early in treatment or soon after exposure the immunological response is sufficiently rapid to modify or prevent respectively the disease in the majority of cases as evidenced by the following—49 of 53 cases treated during the first or second week did not develop whooping or vomiting.

Of 70 cases treated during the third or fourth week, 30 became symptom free after the completion of injections while the remainder showed marked improvement but continued to run a mild modified course of whooping cough. Cases treated during the fifth week showed no benefit.

When used for prophylaxis only 3 out of 14 developed the disease and two were mild atypical cases.

# VICHY-CÉLESTINS

THE WORLD RENOWNED

**FERMENTATIVE**

When the secretion is vitiated in quality and the motricity of the stomach weakens that organ dilates and the gastric stagnation allows the micro-organisms of many ferments to develop. Quite a series of acids are then to be met with (butyric lactic acetic etc.) which not only irritate the mucosa but further after their passage into the intestine

NATURAL VICHY SALT for  
Drinking and Bath

NATURAL MINERAL WATER

**DYSPEPSIA**

become absorbed by the lymphatics and swept into the circulation. Vichy-Célestins, by its slightly stimulating action, clears out the stomach and thus avoids stagnation and consequent fermentation. As, in addition to doing this, it modifies stomatal metabolism the secretions return little by little to their normal physiological condition.

## How We Assist in the Purchase of Medical Practices

Scotland's Oldest Insurance Company is prepared to assist Doctors in the buying of Medical Practices or Partnerships. The purchase price is repayable over a term of years, and a Life Assurance Policy is taken out as a collateral security. This scheme makes it unnecessary for a Doctor to approach his friends to act as guarantors, and enables him to pay for his practice out of income. After the repayment of the loan, the Life Policy becomes a valuable asset to the Doctor.

Many Doctors have already established themselves in practice with the aid of the "Caledonian" Scheme. The Interest Rates are particularly moderate. The Accountant's charges for investigating the practice and the Legal Fees for preparation of the deeds and documents in connection with the Loan are paid by the Company in completed cases. Arrangements can be made to meet special cases.

Full particulars on application to the Head Office or to any of the Company's Branch Offices.

# Modern Iron Therapy

Iron Jelloids' are an elegant and reliable means of administering the protocarbonate of iron. The preparation has none of the disadvantages of Pil Blaud. The iron content remains fresh and unoxidized indefinitely and

injury to teeth is avoided.

The 'Jelloids' are highly effective in the treatment of achlorhydric anaemia and indeed in all the simple anaemias in which massive iron therapy is indicated.

# Iron Jelloids

You are cordially invited to apply for samples for clinical test

The Iron Jelloid Company Ltd King George's Avenue Watford Herts

## "LIVEROID"

BRAND

### PREPARATION OF LIVER

"LIVEROID" is a concentrated preparation of the uncoagulated juice of liver, in combination with other blood and nerve-forming substances. Usefully prescribed for —

Pernicious anaemia and all forms of megalocytic anaemia characterised by high colour index  
Normocytic or secondary anaemias due to loss of blood from any cause  
Microcytic anaemias in which iron therapy combined with liver is desirable  
General debility, neurasthenia or weakness

"LIVEROID" is pleasant to take, and can be given in the form of an appetising beverage.

## PERSISTENT ERUPTIONS QUICKLY RELIEVED ★

Because it contains a perfectly natural antiseptic—distillates of peat—Sphagnol Ointment has a rapid and beneficial effect on skin eruptions. It has a twofold action. From the first dressing it soothes irritation and burning sensations. Then as its antiseptic peat distillates penetrate the local treatment effectively assists in several measures to clear away the toxic matter which is the source of the trouble. We have on record many cases in

which a decided improvement has been shown after only a few days and where before a week had elapsed marked betterment had resulted.

In case you have had no personal experience of Sphagnol, we shall be pleased to send you a clinical size sample for test if you will write to Peat Products (Sphagnol) Ltd, Dept. B.M.J. 3, 21 Bush Lane, London, E.C.4

## ST. ANDREW'S HOSPITAL FOR MENTAL DISORDERS NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President THE MOST HON THE MARQUESS OF EXETER CMG ADC

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients who are suffering from incipient mental disorders or wish to prevent recurrent attacks of mental trouble, temporary patients and certified patients of both sexes are received for treatment. Careful clinical, biochemical, bacteriological and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

### WANTAGE HOUSE

This is a Reception Hospital in detached grounds with a separate entrance to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorder. It contains special departments for hydrotherapy by various methods including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical Bath, 11 miles treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra Violet Apparatus and a Department for Diathermy and High Frequency treatment. It also contains Laboratory for Biochemical, bacteriological and pathological research.

### MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 600 acres. Milk, meat, fruit and vegetables are supplied to the Hospital from the farm, gardens and orchards of Moulton Park. Occupation Therapy is a feature of this branch and patients are given every facility for occupying themselves in farming, gardening and fruit growing.

### BRYN-Y-NEUADD HALL

The residence house of St. Andrew's Hospital is beautifully situated in a park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North West side of the Estate a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses and bowling greens. Ladies and gentlemen have their own gardens and facilities are provided for handicrafts such as carpentry, etc. For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton) who can be seen in London by appointment.

## NORTHUMBERLAND HOUSE, GRELN LANS, TINSBURY PARK, N4

A PRIVATE HOSPITAL for the treatment of mental and nervous illnesses. Conveniently situated and easy of access from all parts. Six acres of ground, highly situated facing Tinsbury Park. Voluntary and Temporary Patients received without certification. Occupational Therapy, Psychotherapy, and other modern forms of treatment. Telephone STAMFORD HILL 2688. Telegrams SUBSIDIARY LONDON. Convalescent Home KILARSNEY COURT DOVER. For further particulars apply to the Medical Superintendent.

## COURT HALL, KENTON, near EXETER,

for the treatment of eight Ladies, voluntary, temporary, or certified patients. Large gardens and own dairy.

CLIFDEN TEIGNMOUTH for early and convalescent cases. A well-appointed house with spacious balconies and extensive views of the South Devon coast. Sub-tropical gardens, own dairy in 25 acres. Private road to beach.

Resident Physicians: BERTHA M. MILES M.D., B.S. Starcross 59. ANNE S. MILES M.R.C.S., L.R.C.P. Teignmouth 289. Telephones.

## THE COPPICE, NOTTINGHAM HOSPITAL FOR MENTAL DISEASES

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Occupational Therapy. Voluntary and Temporary Patients received. Tel. 64117. For terms etc. apply to the Medical Superintendent.

## FENSTANTON, CHRISTCHURCH ROAD, Streatham Hill, S.W.2

A Private Home for the Care and Treatment of a limited number of Ladies with Mental and Nervous Disorders. Certified Voluntary and Temporary Patients received. Large Manor with 12 acres of grounds (See Medical Directory p. 2312). Apply Resident Physician. Telephone: Tulse Hill 7181.

## STRETTON HOUSE.

Church Stretton, Shropshire

A PRIVATE HOME for the treatment of Gentlemen suffering from Mental and Nervous Illness including the allied disorders of Alcoholism and the Drug Habit. All types of early Mental and Nervous cases are received without certificates as Voluntary Patients under the provisions of the Mental Treatment Act 1930. Bracing hill country. See Medical Directory p. 2328. Apply to the Medical Superintendent. Phone 10 P.O. Church Stretton.

## HILL END HOSPITAL AND CLINIC FOR THE PREVENTION AND TREATMENT OF MENTAL AND NERVOUS DISORDERS (2.0 miles from London)

Ladies suffering from all forms of MENTAL ILLNESS are received for treatment on private lines as Voluntary, Temporary or Certified Patients at the Hill End Hospital. Convalescent or mild cases can be treated in a delightful country mansion with extensive grounds known as

### HIGHFIELD HALL,

situated about a mile away from the Hospital. FEES TWO TO THREE GUINEAS PER WEEK. For further particulars apply to the Medical Superintendent. W. J. T. KIMBER, L.R.C.P., D.P.M.

ST ALBANS, HERTS

## BARNWOOD HOUSE GLOUCESTER

A REGISTERED TREATMENT OF LADIES suffering from NERVOUS and MENTAL ILLNESS. Within two miles of the G.W. Railway and L.M.S. Railway Stations at Gloucester the Hospital is easily accessible by rail from London and all parts of the United Kingdom. It is beautifully situated on the foot of the Cotswold Hills and stands in 25 acres of grounds of over 300 acres. Voluntary Patients of both sexes are also received for treatment. Special accommodation for Lady Voluntary Patients is provided at the MANOR HOUSE which is a private grounds and is entirely separate from the Main Hospital. For particulars as to terms apply to G. W. I. H. FLEMING M.R.C.S., L.R.C.P., D.P.M., Medical Superintendent. Telephone No. 6207 Barnwood.

## CHISWICK HOUSE, PINNER, MIDDLESEX

Telephone PINNER 331

A Private Hospital for the Treatment and Care of Mental and Nervous Illness in both sexes.

A modern country house 12 miles from Marble Arch in beautiful secluded grounds. Fees from 10 guineas per week inclusive. Cases under Certificate. Voluntary and Temporary patients received for treatment. Douglas Macaulay M.D., D.P.M.

## BAILBROOK HOUSE, BATH.

For sufferers from Nervous and Mental disorders with or without certificates. The house is gloriously situated in the grounds of 20 acres with views of the City and the Avon Valley. (See Medical Directory page 2328). For terms apply to G. W. I. H. FLEMING M.R.C.S., L.R.C.P., D.P.M., Resident Physician. Telephone Bath 733.

# THE RESIDENTIAL TREATMENT OF ALCOHOLIC & DRUG ADDICTION

# Effective VACCINE THERAPY

without untoward reaction

The high standard and rapidity of the immunity response from Dissolved Vaccines G. L. are due to two factors. first, that the organisms, being in solution, are available for antibody production immediately upon injection, second, that being detoxicated, the vaccines can be given in adequate dosage without producing unfavourable reaction

In each cc, the DISSOLVED VACCINES G. L. listed below contain in solution and detoxicated the antigens of the following organisms (stated in millions)

## ACNE & STAPHYLOCOCCUS

## SURFACE AND RADIOLOGICAL ANATOMY

By A. B. Appleton, M.A., M.D., Professor of Anatomy in the University of London, W. J. Hamilton, M.D., F.R.S.E., Professor of Anatomy in the University of London and I. C. C. Tchaperoff, M.D., D.M.R.E., Assistant Radiologist, St Thomas's Hospital London

9 in by 5½ in cloth, 388 illustrations of which 47 are in colour, 15s net

### Extracts from early reviews

We regard this as an ideal book. Authors publisher and printer have left nothing undone to make this volume as nearly perfect as it was possible to make it. It has our warmest recommendation.  
 —*Medical Times*

The illustrations—so important in a work of this type—are of a high standard, and colour has been skillfully used to make certain anatomical aspects clear. The authors and publishers alike must be congratulated on a splendid addition to anatomical literature.  
 —*The Practitioner*

'This book is easily the best value for money we have seen for a long time. For 15s are given 388 illustrations in colour and monochrome. They are superbly reproduced by a new process which emphasizes details. We have never seen better radiograms. No one can fail to benefit from a study of this book particularly students and practitioners.'

## THE MEDICAL BOOK CLUB

The newly formed Book Club for the Medical Profession only Medical Students will also be accepted No Subscriptions or Membership entertained from the general public

The object of the Club will be to supply Members with the most up-to-date and modern books on Medicine and Medical Science Each book will be the work of a world-famous Specialist and will be chosen by a Committee Publications will also include translations of important foreign works that have not yet appeared in English

By joining the Medical Book Club, Members will be able to obtain books normally published at One to Three Guineas a volume at ONE-QUARTER to ONE-SIXTH of the usual prices

Books published by the Club will NOT be obtainable elsewhere One Book a Month will be issued, and Members need not retain any book unless it is approved

Full details and descriptive folder will be sent upon receipt of a postcard addressed to The Secretary, MEDICAL BOOK CLUB, 34, Great James Street, London, WC1

Just  
Issued**HERMAN'S**Just  
Issued**Practice of Urology**

**Just Off Press!**—Dr Leon Herman is Professor of Urology in the University of Pennsylvania Graduate School of Medicine. His new book is a record of his own clinical experience. It is a practically arranged presentation that General Practitioner, Surgeon and Specialist alike will pronounce decidedly helpful in solving their daily problems of practice.

You will find here the most recent approved methods and procedures. Fundamentals are stressed to bring out important clinical facts and particular attention is given to diseases and conditions that not infrequently present themselves to you for treatment.

Dr Herman details each method of examination, its technique and what it discloses. Cystoscopy, Urography, the Urine are all fully described. An entire section is devoted to instrument techniques, including operative cystoscopy, with specific instructions on preparation of the patient, anaesthesia, analgesia, preparation of instruments and their use. Electrolurgy, irradiation, diathermy are included along with modifications necessary to meet special conditions.

Dr Herman gives you precise clinical pictures, causes, symptoms, diagnosis and proper therapeutic measures. He gives you actual prescriptions, detailed diets, chemotherapy, such as the use of sulphamane, vaccine therapy, pelvic hygiene, use of solutions, injection treatment, hygienic measures, etc. Of special importance are the six chapter section on gonorrhoea in the male, the pre and post section on the prostate gland and the full consideration of venereal ulcerations. It is magnificently illustrated.

Octavo or 923 pages with 756 Illustrations on 704 figures

Cloth 4. net

**TEXTBOOKS for STUDENTS****"MACCALLUM"****Textbook of Pathology**

"The book expresses the personal impression of a pathologist of rich experience. He feels with this book that the writer is dealing with what he has himself seen and pondered. The publishers have given us a book that is a joy to handle and the author a book that is a joy to read."  
—SOUTH AFRICAN MEDICAL JOURNAL

**SIXTH EDITION**

By W. G. MACCALLUM, M.D., Professor of Pathology and Bacteriology, Johns Hopkins University. Octavo or 1277 pages. 697 Original Illustrations many in colours. Cloth 42s. net.

**"RANSON"****Anatomy of Nervous System**

"At times the reviewer feels a more than usual likelihood of gratitude to his editor for introducing to his notice such a good book. This is one of the best. The great character of Ranson's book is its thoroughness. All students of neurology will find this book almost indispensable."  
—IRISH JOURNAL OF MEDICAL SCIENCE

**FIFTH EDITION**

By STEPHEN W. RANSON, M.D., Professor of Neurology, Northwestern University Medical School. Octavo or 401 pages. 331 Illustrations, some in colour. Cloth 27s. 6d. net.

**"HOWELL"****Textbook of Physiology**

"The subject matter is presented in a very readable and interesting way. It is a book of reference and a book of study. The book is a good preparation for the student of physiology and for the student of medicine."  
—LANCET

**THIRTEENTH EDITION**

By WILLIAM H. HOWELL, Ph.D., M.D., Professor of Physiology, Johns Hopkins University. Octavo or 1100 pages. 305 Illustrations many in colour. Cloth 50s. net.

**"AREY"****Developmental Anatomy**

"Dr Arey's book is a most valuable and useful book. It is a book of reference and a book of study. The book is a good preparation for the student of anatomy and for the student of medicine."  
—LANCET

**THIRD EDITION**

By LESLIE B. AREY, Ph.D., Professor of Anatomy, Northwestern University. Octavo or 953 pages. 110 Illustrations on 47 figures many in colour. Cloth 27s. 6d. net.

TABLE WATER**

—a natural water of tonic properties, used extensively by athletes and invalids in Sweden

Supplied by Special Warrant to  
H.M. the King and H.R.H. the  
Crown Prince of Sweden and also  
to H.M. the King of Denmark

**RAMLOSA**

**50 YEARS' REPUTATION FOR MEDICINAL AND TABLE USE**

This famous natural mineral water is bottled at the source and slightly aerated with pure Carbonic Acid. The characteristics of "Ramlosa" are a relatively high Sodium Carbonate content in combination with an uncommonly low content of Calcium and Magnesium Salts (practically no lime) and a virtually complete absence of iron. "Ramlosa," in consequence, avoids the fault of certain natural mineral waters which upset the digestion by partially neutralising the hydrochloric acid in the gastric juice. "Ramlosa" considerably increases the amount of urine and is therefore indicated in the treatment of diabetes, gout, kidney troubles and other metabolic disorders, as well as in rheumatism and in conditions where a large supply of fluid is of importance as a mild form of urticant physical therapy.

## This is the brother of the round tin

The only difference is—it isn't round. So let us again call your attention to 1 The vacuum—hear the hiss, on opening 2 The handy shape and smooth turned-over rims 3 The ease with which the tin opens, and the way the lid snaps on again And 4 the tobacco itself. Here, of course, you're the judge. But, frankly, we like it ourselves. For smokers just can't get tired of its pleasant, natural flavour. You can get it in the original 1 lb. ed form or Ready Rubbed—at 2/- 12 oz. tin

To give you a **better**

**Therapeutic**

**result...**

In the treatment of all debilitating conditions and in diseases of malnutrition the foremost authorities are agreed that the source of radiation should be as near as possible approximate the U V wavelengths found in the Solar spectrum. The shorter or non-terrestrial wave band merely brings about a too rapid erythema before the longer and essential wavelengths have become fully effective. In the "BIOSOL" the wavelengths below 2900 AU are completely cut off by means of the "DORNO" filter. When on the other hand a strong erythema is required—as in the treatment of skin diseases, the "DORNO" filter (exclusive to the "BIOSOL") has only to be removed. In this way provision is made for the two wave bands which correspond to the two classes in which cases for actino therapy can be roughly grouped. The "BIOSOL" thus rationalizes technique to quite a new degree and is the obvious choice for the modern clinic.

# Duo-Therapy

## Sunshine for

### your patients

There is no reason why you should go without the benefits which actinotherapy brings to both practitioner and patient. But your results depend largely on effective apparatus. No skill or study will enable you to overcome self-imposed defects due to inadequate or outworn equipment.

Specify the Hanovia Duo-Therapy Unit and have a lamp which is always dependable, always ready for use, always constant in its high intensity of ultra-violet radiation. Remember that this Unit combines the most modern ultra-violet ray lamp (the self-starting electronic Alpine Sun) with the standard therapeutic infra-red lamp (the new Sollux Lamp, Model V). So the Duo-Therapy Unit enables you to apply any group and combination of rays needed for modern actinotherapy, in full therapeutic intensity, following the best technique, and using a dependable, responsive instrument.

This is why most practitioners now specify the Duo-Therapy Unit for their consulting rooms, and why so many users of older ultra-violet lamps avail themselves of our part-exchange terms for replacement with this up-to-date Unit.

The coupon is for your  
convenience

HANOVIA, Ltd,

For support of the lower  
abdomen -

*panties*  
designed by J. Roussel

The modern garment for  
health and beauty

Women will always seek beauty of figure. In the Panties designed by Roussel they have a garment that gives a fashionable line, and one that their medical adviser can approve. Roussel Panties are woven to give support to the lower abdomen without dangerous pressure on the abdominal organs. Being woven to measure they do not restrict thighs or waist. The special elastic tricot from which they are woven exerts a gentle massaging action which stimulates circulation, assists in dispersing fat and encourages the natural eliminative functions. If you would like to know more about Roussel Panties and other figure-control creations designed by Roussel please phone or write for a copy of our beautifully illustrated Catalogue. Prices from 2 Guineas. A reduction of 2s. in the £ is made on purchases for person use by members of the Medical Profession. Write to Dept. ME.

# SAFE MILK...

Milk that is pure is full of blessings. Doubtful milk is a menace. With Nestlé's, care and cleanliness begin at the very beginning. Not only the farms but the feeding is sternly supervised. In the snow-white condenseries down in the shires, the fresh meadow milk is handled like something precious. Rich with all its cream and goodness it is sealed beyond reach of danger. No harm, seen or unseen, can come to it. It is milk as it should be—utterly pure. Safe, sealed, signed with a name you can trust.

## NESTLÉ'S MILK

### VICHY-CÉLESTINS

THE WORLD RENOWNED

NATURAL MINERAL WATER

This Natural Alkaline Mineral Water may be prescribed with absolute confidence with regard to its purity and natural condition. It is bottled at the Springs under the most careful supervision, and to ensure fresh supplies is imported with regular frequency.

NATURAL VICHY SALT for  
Drinking and Baths

The VICHY WATERS, being almost devoid of Sulphates, are most agreeable to the taste, and are daily relied upon by Physicians the world over in the treatment of Gout and Rheumatism and for Affections of the Liver, Stomach, etc.

VICHY DIGESTIVE PASTILLES  
prepared with Natural Vichy Salt

CAUTION—Each bottle from the STATE SPRINGS bears a neck label with the word 'VICHY-ETAT' and the name of the SOLE AGENTS

# ASCORBIC ACID B.D.H.

(VITAMIN C)

**A**SCORBIC ACID B D H is available in forms suitable for administration in cases of specific deficiency and in cases in which the vitamin appears to exert a beneficial effect, although no pronounced deficiency is necessarily demonstrable.

In cases in which there are no marked symptoms of gastric hypo-acidity the acid itself should be given orally, for this purpose, tablets of two strengths are available. In other cases the sodium salt should be given intravenously, subcutaneously or intramuscularly, for this purpose, ampoules of solution and tablets for the preparation of solutions for parenteral use are available.

Ascorbic Acid B D H is available also as a constituent of Radiostoleum Emulsion with Vitamin C and of Multivite.

*Descriptive literature and samples of any of the above-mentioned products containing Ascorbic Acid B D H will be supplied on request.*

# THROMBIN-COAGULANT-MAW DRESSINGS

## FOR THE MAJOR OPERATION OR THE MINOR CUT

Some time ago we announced the production of Thrombin-Coagulant-Maw a preparation of remarkable efficiency for clotting blood

We now offer a range of Surgical Dressings known as Thrombin-Coagulant-Maw Dressings, to which this preparation has been applied with such regard for the scientific principles concerned, both chemical and physiological, that we venture to suggest a new method of treatment has been found

THE PHYSIOLOGICALLY CORRECT FIRST DRESSING

Whenever a wound is accessible to the application of a Dressing, T C M Dressings will be found of great value in all cases requiring hæmorrhage control. They are very reasonable in price and represent a true economy of your own time and money, whenever hæmorrhage has to be treated

## ACRIFLAVINE 'B.D.'

Acridine 'B D' is a member of the acridine group of dyestuffs, it possesses a unique property in that its bactericidal power is enhanced in the presence of serum

In the dilutions at which Acridine 'B D' is highly bactericidal it is also non-toxic

A solution of 1 in 1000 applied as a wound dressing is remarkable in its

effectiveness, it will also clear up with extreme rapidity such local septic conditions as eczema, impetigo, pediculosis, scabies, pyoderma, sycosis barbae, folliculitis, pemphigus neonatorum, ulcus molle and impetigo contagiosa

Moreover, infections due to meningococci and gonococci yield to treatment with unfailing regularity

*Literature on request*

## ALASIL

### Safe Salicylate Therapy

THE popularity of acetyl salicylic acid is undoubtedly due to the fact that it is one of the safest and most effective non narcotic analgesics available. Too often however its use has been discarded by the physician on account of its tendency to irritate the stomach and because entirely pure preparations are not always available.

Alasil provides the beneficial therapeutic effects of pure acetyl salicylic acid in such a form that it is acceptable even by disordered digestions. This tolerability is due to the fact that it combines calcium acetyl salicylate—the least irritating salicylate compound—with Alacol, a potent gastric sedative and antacid.

Since Alasil is better tolerated than acetyl salicylic acid its use can be pushed or prolonged to a much greater extent than the latter.

Alasil is therefore an analgesic, antipyretic and anti-rheumatic which can be employed with complete confidence in all the many conditions in which such an agent is indicated.

# NEW BLOOD TRANSFUSION TECHNIQUE

**THE BAXTER BLOOD TRANSFUSION SET** An apparatus for the indirect transfusion of citrated blood in which the blood is sealed against contamination from the moment it leaves the donor's vein until it is injected into that of the recipient.

Baxter's New Blood Transfusion Set brings you unequalled simplicity and safety sealed against contamination throughout procedure. The advantages inherent in the SAFETY and speed of transfusions under the Baxter method can hardly be exaggerated.

## OBSTACLES OVERCOME

Hand in hand with the growing use and widening approval of the indirect method for blood transfusion comes the need for a simplified apparatus to make transfusions easier for you and safer for your patients.

The greatest objection to the indirect method has now been permanently overcome. By the modern Baxter method blood is obtained citrated and injected under the same seal—risk of contamination is eliminated—risk of clots is minimised. The blood remains sealed in its

Vacoliter container from the moment it leaves the donor's vein until it is injected into that of the recipient.

## NEW USE FOR AN ALREADY USEFUL INSTRUMENT

Here is the interesting story of the development of the new Baxter Blood Transfusion Set—Dr W B Cooksey, of Harper Hospital Detroit, long an enthusiastic user of Baxter's Intravenous Solutions in Vacoliters (RTM), saw the remarkable possibilities of the 'Vacoliter' in blood transfusions. He devised a metal handle and a specially designed rubber stopper, fitted them with a negative pressure bulb and an intake tube, attached the whole to a 500 cc Vacoliter, and there was a Blood Transfusion Set that is simplicity itself.

We shall be pleased to send upon request an illustrated folder describing Baxter's Blood Transfusion Set in detail.

# THE MEDICAL CASE FOR A WHOLE WHEAT CRISPBREAD

**W**HEAT has always been Man's first choice among the cereals, whenever climatic conditions did not prevent his getting it. That remains true of all bread, either white or wholemeal, either soft or biscuit-crisp. And Vita-Weat, the wheaten crispbread with the **WHOLE** of the wheat left in it, has advantages which entitle it to a very high place among the staple foods of the world.

## ITS CALORIFIC VALUE

Bread is the 'energy component' and Vita-Weat since it contains only 3 per cent of water, has a fuel value nearly twice that of ordinary bread—according to *The Practitioner* its caloric value is 2,132 per lb.

Each section of such a crisp bread—each 'slice,' so to speak—has a caloric value of 37. That is to say that in meeting what is probably the greatest requirement of a national staple food Vita-Weat is almost twice as effective as the softer kinds of wheaten bread.

## STARCH AND DIGESTION

A crisp bread, obviously, calls for a more thorough chewing than a soft 'crumb' bread and mastication is therefore more healthily promoted. The starches and cellulose in Vita-Weat are also converted into a more digestible form by the special processes which go to make a good crispbread—just as oats and crust have become greatly more digestible than bread in its quite unconverted starch form. While *all* the wheat berry is used the bran and fibre are thoroughly disintegrated.

The result is, therefore, that the weight which quantities of unconverted starch places on the

digestion is almost entirely eliminated. Where Vita-Weat has been prescribed

## VITA-WEAT AND ITS ADVANTAGES

In addition to these great advantages of caloric fuel-value and digestibility Vita-Weat retains the protective elements of the wheat berry and is frequently rejected in the refining of white flour. Protein, vitamins and minerals in such a form as normal deficiencies are prevented and the source of this crisp bread as a food is therefore retained. The use of Vita-Weat can be highly recommended desirable in cases of malnutrition, indigestion, infection, lack of appetite, protracted convalescence and as a food of protection for the young and the aged.

*All the wheat berry is used in the manufacture of Vita-Weat. ## NASAL SINUSITIS IN CHILDHOOD\*

By

JAMES CROOKS, F.R.C.S.

*Aural Surgeon The Hospital for Sick Children Great Ormond Street*

Since nasal accessory sinusitis is almost always the result of colds, other upper respiratory infections such as influenza, or the exanthemata it is proper to emphasize that the avoidance and correct treatment of these conditions are of the utmost importance.

Children often manage to escape with few infections during their early lives but it is common to find that their first year or so at school is constantly interrupted by colds. This is scarcely to be wondered at for it is at school that they first encounter the millions of organisms which exist where people are herded together. In such places as schools, trains and cinemas it must be almost impossible to breathe air which has not already been in and out of someone else's lungs or which does not contain droplets from the coughs and sneezes of those who have colds. So far the human species has not been able to develop an innate immunity to the organisms that cause upper respiratory infections. It has scarcely had time to do so for, bearing in mind the history of mankind it is only recently that people have lived in such close proximity to each other. At a children's hospital such as that of Great Ormond Street it would not be an exaggeration to say that one third of the patients are suffering from disease which is the result of inhalation of micro organisms.

### Frequency

How frequent is sinusitis in children? That it is common in the early years of life has been demonstrated by many different workers. J. H. Ebbs (1938) recently published the results of the examination of the sinuses of 496 children post mortem. He found disease in 152 instances or 30.6 per cent. Other investigators have submitted a series of children to antrum puncture by this means. Mollison (1922) observed that 22 per cent had muco-pus in the antra and Carmack (1931) 30 per cent. In a series of 100 children at Great Ormond Street I found that twenty-four had muco-pus in the antra (Crooks and Signy, 1936). All these children were from a tonsillectomy list and obviously had something wrong with their noses or throats, or they would not have been undergoing that operation. Since it had been said that removal of tonsils and adenoids cures sinusitis in children and also that this condition is only temporary, I punctured the antra of these twenty-four children again six months later to test these statements and still fifteen of them had muco-pus. Therefore neither of these statements is true. During last year antrum infection was proved by exploratory puncture in over 500 children at my out-patient

department and approximately the same figure applies to several preceding years.

We have been slow to recognize the importance of sinusitis in childhood. It has long been known that it is common in adult life and it stands to reason that children are more liable even than adults. They are more susceptible to colds and their sinuses drain less readily during a cold since the small nose is so easily blocked by mucosal swelling. We know how frequently otitis media occurs in the young, and the middle ear is after all only a specialized sinus off the nasopharynx. And the sinuses are all present in childhood: the antrum exists at birth and by the third year is a fair sized cavity, the ethmoid labyrinth contains well denned cells at birth and the sphenoid is a definite cavity in the third year. The frontals vary greatly in development but by the age of 5 or 6 there is usually a good sized cavity. Therefore there is every reason to expect sinusitis in early life.

### The Causation of Sinusitis

By far the commonest cause of sinusitis is a cold, or colds. Influenza particularly in some epidemics is often responsible for the onset and sinusitis may follow any of the infectious diseases which are accompanied by upper respiratory inflammation particularly whooping-cough. Bathing in infected water is another mode of infection but so far as children are concerned antrum infection from bad teeth does not arise. Lastly allergic rhinitis may give origin to secondary sinusitis.

It is true to say that with every nasal cold there is sinusitis. How could it be otherwise when the mucous membrane lining the sinuses is continuous with that of the nose? A radiograph taken during a cold will almost always show some thickening of the mucous membrane in the antra. But usually as the cold gets better the sinuses return to normal. When however there is retention of exudate in a sinus during an acute infection or if inflammation persists in such a cavity after the general nasal infection has settled sinusitis merits separate consideration. Retention of exudate under tension due to closure of the ostium by inflammatory swelling gives rise to headache, localized pain and tenderness. Persistence of inflammation in a sinus with an open ostium induces nasal congestion and discharge. The latter is often of the nature of an overflow, the matter in the sinus accumulating until it has reached the level of the ostium. Normally the cilia wipe the exudate towards the ostium against gravity if necessary. When they are inflamed they are incapable of doing this.

It is essential to bear in mind that pus in a sinus is strictly speaking outside the main body cavity. It is in

\* Lecture delivered to the City Division of the British Medical Association March 1 1938.

no way comparable to inflammation in a long bone, for instance. Provided the ostium is open drainage is present and there is rarely any increase of temperature or localized pain. These manifestations arise only when the ostium is blocked, and then the condition more closely resembles an abscess elsewhere.

The anatomical peculiarities of an individual nose may make it more liable to sinusitis than is normal. For instance, a deviated septum which presses upon a middle turbinate may completely block the ostia of several sinuses when there is nasal congestion. A small and crowded nose is less likely to maintain adequate drainage for the sinuses during a cold than a good roomy nose, and, of course, a sinus may have an abnormally small ostium. And last but by no means least some people are highly susceptible to upper respiratory infections, and appear to have little or no immunity to colds. They are obviously candidates for sinusitis.

### Bacteriology

It is interesting to compare the bacteriology of sinusitis with the bacteriology of the nose. When I made my observations upon a series of children nasal swabs were taken from them at the time the antra were aspirated. Whereas the commonest organism found in the nose was the staphylococcus, the pneumococcus was much the most frequent organism in the infected antra. Next commonest in the sinus was the Pfeiffer bacillus, but it was rare in the nose. The *Micrococcus catarrhalis* and the *Bacillus hoffmanni* were common in the nose but rare in the sinuses. The streptococcus was a frequent cause of sinusitis but was not so often found in the nose. The usual causes of sinusitis were therefore the pneumococcus, the Pfeiffer bacillus, and the streptococcus. The common organisms in the nose were the staphylococcus, the *Micrococcus catarrhalis*, and the *Bacillus hoffmanni*. The pneumococcus produces a very thick yellow pus, and one wonders whether this fact gives it pre-eminence as a cause of sinusitis, the pus being too thick to escape from the ostium readily.

There is one special peculiarity about the pathology of sinusitis in children: the bone surrounding the sinuses is more porous than in later life, and osteitis is more likely to arise. I will now proceed to the clinical manifestations.

### Acute Sinusitis

Acute sinusitis meriting separate consideration from a generalized inflammation of the nose, sinuses, and throat is comparatively infrequent in childhood, and it only calls attention to itself during the course of such an infection when the discharge cannot escape from the sinus. This happens, of course, when the ostium becomes blocked owing to the swelling of the mucosa encroaching on the narrow opening. It therefore occurs typically at the height of an acute cold or influenza.

### SYMPTOMS

These vary with the sinus involved, and usually consist of severe headache, localized pain, tenderness, and an increase in fever. If the antrum is at fault there may be swelling of the cheek and oedema of the orbit. Sometimes osteitis of the maxilla results. An acute block in the ethmoids with osteitis is not very uncommon in the first year or two of life. When severe there is a tender swelling over the upper part of the side of the nose, and the orbit is closed by great oedema. Sometimes the eyeball is immobilized. On several occasions the diagnosis

of cavernous sinus thrombosis was made. It is important to recognize the nature of the illness, because external opening of the ethmoids results in recovery, while neglect of it may end in cavernous sinus thrombosis and death.

### TREATMENT

In the first place treatment is conservative. In the great majority of instances the ostium can be made to open and let out the discharge without surgical intervention. The patient will of course be in bed, and it is important to maintain an even temperature in the room. Sudden changes of temperature increase nasal congestion. The main object of treatment is to shrink the inside of the nose till the discharge comes away. There are many preparations of use for this purpose—they usually contain ephedrine and volatile oils. A benzedrine inhaler is effective, and children like it. Inhalations of menthol in hot water are helpful if the child is old enough to use them. In addition the middle meatus of the nose should be shrunk by the application of a cotton dressed probe dipped in cocaine 10 per cent and adrenaline 1 in 1,000. Only if these measures fail after trial for a few days should surgery be resorted to, and then it should be as simple as possible—for instance, aspiration of the antrum, but not lavage, which may spread the infection.

It is obvious that acute sinusitis may pass on to a chronic condition in which there is inflammation of the mucous membrane, although drainage has been established.

### Chronic Sinusitis

Chronic sinusitis is so often found in the catarrhal child who is liable to colds that it must claim our chief attention. The pathological condition present is catarrhal, or, more rarely, suppurative, inflammation of one or more of the sinuses with continued discharge into the nose. Most often the trouble lies in the antrum. I had come to that conclusion clinically, and was pleased to see that Ebbs in his series of necropsies had found that the antrum was involved more often than the ethmoids and sphenoids added together.

### SIGNS AND SYMPTOMS

A series of 100 children with sinusitis at Great Ormond Street was analysed for signs and symptoms of chronic sinusitis, and the following figures are based on this examination. Subsequent observations on many hundreds of children have confirmed them.

**Nasal Discharge.**—The most frequent symptom was nasal discharge, and of the 100 children eighty-four suffered from it. There is one point to beware of in children. A child hates to have his nose blown, and will try his best to avoid being attacked with a handkerchief. Therefore he tends to sniff nasal discharge backwards into the throat. It is not enough to ask a mother if the nose runs, you must ask if the child sniffs. Very often the mother says there is no discharge, but that the nose is stuffy and full of catarrh. The secretion may be mucoid and clear or yellow and sticky, and is sometimes purulent. Since sinusitis is so often bilateral—the antrum was involved on both sides in sixty-one children and on one side only in thirty-nine cases in this series of 100—the discharge is usually from both sides of the nose. The child is hardly ever free from catarrh, except perhaps for a few summer months. Each cold is accompanied by a streaming nose, which takes several weeks to improve. In short, children with sinus disease are catarrhal, and one could almost go further and say that children with catarrh have sinusitis. In these eighty-four children the average duration of nasal catarrh was two years.

**Colds**—Of the 100 children eighty three suffered from frequent colds. Sometimes the mothers said they were never free from cold—another way of stating that they had chronic catarrh. Colds are the cause of sinusitis and so we would expect these children with sinusitis to have colds. But sinusitis is also a cause of colds. Sometimes after washing out an antrum a child develops a cold or tonsillitis: active organisms have been released. It is therefore obvious that a discharging sinus may cause a cold and the vicious circle is complete.

**Cough**—Eighty-two of the 100 children suffered from cough. It is a severe hacking cough, often resembling whooping-cough, worse at night and on waking and is the result of post nasal discharge through sniffing. If the discharge lies in the nasopharynx the cough is merely a reflex irritation. Unfortunately it may be a much more serious matter. If some Ipiodol is placed in an antrum and the child then goes to sleep some will be found in the lungs next morning. So it is with the purulent discharge from the sinuses. During deep sleep it drops through the open glottis into the lungs and often serious lung trouble develops. Nearly all bronchiectasies have sinus disease. It has never been proved that the sinusitis is the cause of the bronchiectasis but it seems a reasonable possibility. I do not believe in the other theory that coughed up sputum infects the sinuses. Most likely there is some weakness in the respiratory system or lack of resistance to disease which makes both the lungs and the sinuses liable to inflammation.

**Snoring and mouth breathing** were present in 62 per cent and here one must say a word about the adenoid face. It is a pity that such a term was ever coined, for it has misled all of us. The adenoid face is the face of a child with a blocked nose and nothing more. And adenoids are not the most common cause of a blocked nose even in children. The nasopharynx is a big space and it needs a good mass of adenoids to block it up. Occasionally such a mass is found but not more often than say once in every five or six operations for the removal of tonsils and adenoids. On the other hand the nose is a narrow space and is very easily blocked by swelling of the turbinates and accumulation or discharge. In sinusitis the turbinates become swollen, particularly the inferior turbinates over which the discharges flow. In my opinion an adenoid face is more often the result of nasosinusitis than it is of adenoids. Of course the two may go together.

**Sore throats** may occur in sinusitis from mouth breathing and tonsillitis may result from infected post nasal discharge.

**Enlarged cervical glands** are seldom the result of sinusitis by itself. Lymphatic absorption from an intact sinus is not great.

**Headaches** are common and occurred in 44 per cent. They are usually frontal, and are apt to be severe during a cold.

**Otitis media** occurred in forty-four of the 100 children with sinusitis. Trickling as it does over the orifices of the Eustachian tubes it is little wonder that post nasal discharge often leads to otitis media. It is almost an axiom these days that otitis media calls for the removal of adenoids. It also calls for an investigation of the sinuses and one has often seen persistent otorrhoea clear up after treatment of an infected sinus.

**Systemic Effects**—Chronic sinusitis causes general debility characterized by mental lassitude and a change for the worse in temperament. A child with sinusitis is often morose and ill tempered, he is easily tired and has

dark rings under his eyes. Sinusitis does not commonly constitute the focus of infection responsible for such diseases as rheumatism or arthritis. Organisms are not readily absorbed from the sinuses and even the lymphatic drainage is slight.

#### DIAGNOSIS

This rests upon the symptoms in the first place but must be supplemented by certain special observations which are (1) examination of the nose (2) transillumination (3) radiography and (4) puncture aspiration.

**Examination of the Nose and Throat**—Continued discharge from a sinus causes nasal congestion on the corresponding side and of course nasal congestion leads to further retention in the sinus so one expects to see congestion and hypertrophy of the inferior turbinate on the side of the nose corresponding to the sinusitis. The middle turbinate is also often swollen but is less easy to see. In the middle meatus or between the inferior turbinate and the septum there may be an accumulation of mucus or muco pus. A post nasal examination would reveal post nasal discharge. It is difficult to carry out in a child but often enough a blob of muco pus will be seen hanging down behind the uvula. The pharynx is usually red and granular.

**Transillumination** is sometimes useful. If the sinus involved is the antrum and if the condition is unilateral a definite finding is obtained with transillumination. Unfortunately circumstances are not often so favourable for when both antra are infected it is still possible to get a light through them in a child it is powerful enough. And again if they are poorly developed or have unerupted teeth in front of them they appear dull.

**X ray examination** is essential. For general purposes one film taken in the naso-mental position is sufficient. It shows the antra, the ethmoids and the frontals and the cause of any opacity—whether thick mucous membrane only or fluid content. Usually the infected antrum shows a uniform opacity made up of thick membrane and retained secretion. In a child a fluid level is rather rare and indicates a not very thick lining for such a lining would obscure the level. A good radiograph will always

Puncture aspiration of the antrum. This procedure is used for either local or general anaesthesia. The antrum is the most dependent part of the cavity and the fluid is held still.

show disease if it is present and it is unwise to presume a pathological change in a sinus that is clear in such a film.

**Puncture aspiration** of the antrum is the final proof of the presence of infected contents in that cavity. It is not such a delicate test of sinus pathology as a transillumination for many a sinus shows changes in trans-

mucosa in a radiograph but is clear on aspiration or wash. The converse does not hold good. There are two points worth mentioning in regard to puncture-aspiration. It is advisable to culture the fluid aspirated, and it would be useless to aspirate it through the ordinary cannula, since that is contaminated by the withdrawal of the trocar. Therefore a finer cannula is attached to a glass syringe containing sterile saline, and this is passed through the original cannula left *in situ* and the contents are aspirated into the syringe. The position of the head is also important, for the point of the cannula must reach the lowest part of the antrum cavity. This can only be attained by adopting the position I advocate: the child lying on his back with the shoulders on a sand pillow, and the head extended fully (see diagram).

#### TREATMENT

The treatment of chronic sinusitis is in the first place preventive. Colds must be avoided by improving hygiene and general health and resistance. When they occur the nasal mucosa must be shrunk so that the ostia of the sinuses remain open. If subacute or chronic catarrhal sinusitis persists after a cold general medical treatment is indicated. Only if there is retention of inflammatory products in a sinus is lavage necessary. Operation is reserved for chronic suppurative sinusitis.

As an example, take the child who has all the past winter been subject to repeated colds and since the last cold a month or so ago has had continuous nasal catarrh. Examination reveals a debilitated sniffling child with a little cough. The inferior turbinates of the nose are swollen. There is a mucoid discharge seen running down the back of the throat. X-ray examination shows swollen mucosa of the antra, and perhaps the opacity is more marked on one side than on the other, suggesting some amount of retention. What is the correct line of treatment? It should be started by keeping the child in a warm, well-ventilated room for a week, the nose meanwhile being shrunk by repeated applications of shrinking drops and by inhalations of menthol. At the same time a vitamin-containing tonic should be given. After that the child should get out whenever the weather is reasonable, and when he has been doing that for a week, the nasal shrinking being continued with, he should go to the seaside. After a month or two on the south coast a radiograph would probably show the sinuses to be clear. Admittedly such expensive and prolonged treatment is out of the question for many children. It so, one may be forced into washing out the antra as the quickest way to get rid of the symptoms. It often works like a charm, but it is no real substitute for the improved general condition and resistance which would have resulted from a holiday at the seaside.

Now consider a more severe example, that of a child who has had constant nasal discharge all the winter. The general condition has suffered a good deal, and a hard barking cough which interrupts sleep at night has developed. Perhaps there has been headache. Radiographs show complete opacity of one or both of the antra. It is unlikely that the line of treatment suggested for the previous case will be rewarded with success. It is necessary to proceed straight away by washing out the sinus in question and there is no doubt that recovery, even if it does not depend entirely on lavage, will come about much quicker because of it. It is quite possible to wash out the antra of children under local anaesthesia. With a very nervous or difficult child it may be necessary to give a general anaesthetic but I rarely have to resort to it, especially in hospital practice. According to the find-

ings on lavage the procedure may need to be repeated several times, usually at weekly intervals. The average number of washes necessary in the 100 children I have quoted was three. The treatment as outlined for the milder case should be given at the same time.

Finally, consider the exaggerated example of a child who has had a purulent nasal discharge for several years, and is found on x-ray examination to have an opaque antrum with chronic changes in the mucosa. In my opinion lavage is again indicated, and should be repeated up to a dozen times if there is improvement rather than that an intranasal operation should be resorted to. Of course, if there is as much purulent discharge on the sixth wash as there was on the first, one would probably feel that more radical treatment was necessary.

What is more radical treatment? It is antrostomy—that is, punching as large a hole as possible in the bone of the inferior meatus, between the nose and the antrum. There is then dependent drainage and a large opening through which it is easy to insert a curved tube for washing. I do not consider it such a desirable operation as it sounds theoretically, at any rate in childhood. The floor of the antrum being higher than the floor of the nose during youth, the opening cannot be made very large unless the inferior turbinate is sacrificed, which I am unwilling to do. Also, the hole in the young bone is apt to close in a month or two. Finally, lavage through the opening is little more pleasant than puncture. In spite of its drawbacks, however, it is an operation which has often been followed by good results.

Lastly, there are those cases, even in childhood, in which such advanced disease of the mucosa of the antrum is present that only its removal will alleviate the symptoms. Then a Caldwell-Luc operation has to be done.

We have been discussing the antrum. It is easier to treat than the other sinuses and enables one to present a scheme of treatment more readily. In addition it is far more frequently diseased than the other sinuses in childhood. Disease in the *sphenoid* is more difficult to diagnose and treat. One depends on radiographs even more than in the case of the antrum. Lavage can be carried out through a straight trocar and cannula.

The complicated structure of the *ethmoids* makes them unsuitable for puncture and lavage. In advanced disease it may be necessary to remove the middle turbinate and open the cells, but in less severe inflammation of the *ethmoids*—and the same applies to the *sphenoids*—Proetz (1931) has worked out a most valuable form of treatment which he calls displacement. The principle is the introduction of shrinking or therapeutic fluids into the sinuses by means of repeated negative pressure applied to the nose, which is filled with the fluid selected. This form of treatment applies particularly to the *ethmoids* and the *sphenoids*, and is of less value in the antrum.

Short-wave diathermy has been used recently, and is of benefit in those conditions of chronic catarrhal sinusitis which are not accompanied by retention of exudate.

#### Prognosis

What is the outlook in sinusitis in childhood? It is obviously much more favourable than in later life, for two reasons: (1) the young tissues recover more quickly and completely, (2) sinusitis in the adult may have been in existence for years before it is diagnosed.

Sinusitis has a bad reputation, and one is told that it is never cured for life. That is obviously because it

does not fall into the ectomy class. Appendicectomy and tonsillectomy leave no room for recurrent inflammation in the organs involved. No doubt removal of the antrum would be followed by a complete cure of antritis. But the cure would be much worse than the disease. It is possible to cure inflammation in a sinus completely by adequate treatment but of course the sinus remains and so does the inherent liability to infection of it which caused the original trouble.

Of the 100 children we have been discussing fifty-two were completely cured—that is they were free of symptoms and final radiographs showed normal sinuses, thirty-two were improved and sixteen remained unchanged.

### Relation of Tonsils and Adenoids to Sinusitis

Even in a short paper one cannot omit referring to the tonsils and adenoids and their relation to sinusitis. The first question that comes to mind is: Does infection of the tonsils and adenoids cause sinusitis? If so it must be either because the adenoids are so large as to block the nasal airway and interfere with ventilation of the sinuses, or because it is a result of surface spread of infection against the normal mucous stream kept up by the cilia. The removal of tonsils and adenoids should cure sinusitis and it should be uncommon among children who have had their tonsils and adenoids removed. I have already mentioned that of twenty-four cases of sinusitis in children only nine cleared up after removal of the tonsils and adenoids and they might have done so without the operation. Of the 100 children with sinusitis forty-one had already had their tonsils and adenoids removed completely. The broad conclusion is justifiable that disease of the tonsils and adenoids is not a common cause of sinusitis and that their removal is neither a preventive nor a cure of the condition.

The second question is: Does inflammation in the sinuses give rise to infection of the tonsils and adenoids? As the post-nasal stream of mucus is over the adenoids and posterior halves of the tonsils the mechanical possibility of such an infection is evident. It is difficult to draw conclusions from the fact that forty-one of our 100 children had previously had their tonsils and adenoids removed. They may have had the operation done for symptoms which should more properly have drawn attention to the sinuses. Even worse they may have developed sinusitis as a result of imperfect technique during the operation of removal of their tonsils and adenoids. One has seen that happen. Infected blood runs into the sinuses and sets up inflammation there.

I believe that sinusitis is a common cause of inflammation of the adenoids and to a lesser degree of the tonsils. The first step in the treatment of sinusitis is the treatment of the sinus itself and not the removal of the tonsils and adenoids. If the latter are infected and fail to respond to such treatment they should be removed. If there is a large pad of adenoids interfering with respiration treatment of coexisting sinusitis is not likely to lead to cure until it is removed.

## A CLINICAL EXPERIMENT IN OESTRIN THERAPY

By

P M F BISHOP, B M, B Ch

Clinical Endocrinologist, Guy's Hospital

Oestrin is now well established as a therapeutic agent but many problems remain to be solved before the most effective mode of administration can be determined. The principle of endocrine therapy is to give the hormone by the most convenient route in such a form and dosage that it will be delivered at the site of effect at a suitable rate in suitable concentrations and over as prolonged a period as possible or desirable. The following case illustrates some of the factors to be considered in the use of oestrin.

On February 27 1936 Mr Frank Cook did a bilateral ovariectomy for cysts of both ovaries on a girl aged 20 who had suffered for some time from irregular menstrual bleeding. Three days later uterine haemorrhage started and continued for three days. Nine days after the operation hot flushes began to appear. Oestrin was first given forty-four days after operation by which time the patient was complaining of about twelve hot flushes a day and during the subsequent two years the case afforded an opportunity for studying the effects of oestrin given by mouth by injection and by implantation. In Chart I the number of daily hot flushes is indicated and is correlated with the dose of oestrin administered.

### The Effective Dose of Oestrin for a Recent Castrate

A consideration of the chart shows that the symptoms as measured by the daily frequency of hot flushes began to come under control when oestrone (mentormon Organon) was given in daily doses of 6 000 IU (0.6 mg) by mouth and after a prolonged period of administration of higher doses remained completely controlled by 3 000 IU daily. The case is particularly suitable for this type of investigation since the daily hot flushes cur e rose rapidly when treatment was discontinued. Later in the patient's history (January 1937 et seq) doses increasing from 1 000 IU of oestrone by injection had an effect on the symptoms and later still (October 1937) 1 000 MU of oestrin by mouth\* (tridesmin Paines and Byrne) was found to be a suitable maintenance dose. Finally the implantation of a 14 mg tablet of crystalline oestrone produced a demonstrable effect lasting over a period of weeks.

Thus it would appear that relatively small doses of oestrin by mouth are effective in controlling the symptoms of acute ovarian deficiency in a castrate. This observation is supported by results obtained in other cases. For instance the administration of 1 000 IU daily for a fortnight followed by 2 000 IU for another fortnight completely relieved the symptoms of a woman of 34 who was suffering from a moderately severe menopause with six hot flushes a day and converted a well marked menopausal vaginal smear into one typical of oestrin.

It is important to determine the minimal effective maintenance dose of oestrin in these cases for the administration of high doses has certain disadvantages.

1 It may induce uterine haemorrhage and the patient suffering from the effects of a natural menopause should be

Oestrin (trihydroxy-oestrin) is less potent when given by injection than oestrone (acetohydroxy-oestrin) but it is more effectively absorbed than oestrone when given by mouth. It therefore appears to be a suitable method of peroral administration of oestrin.

CHART I—Showing the number of hot flushes daily and their correlation with the dose of oestrin administered

warned of this possibility if moderately high dosage oestrin therapy is contemplated

2 It may give rise to certain uncomfortable symptoms such as a feeling of fullness headaches and nausea, which are probably minimal in nature and are due to dosage slightly below that which would produce oestrin withdrawal bleeding

3 It may inhibit the gonadotropic activity of the anterior pituitary gland. The sudden or gradual diminution of ovarian function in the castrate or at the menopause produces excessive gonadotropic activity and it is the disturbance of balance between these two endocrine secretions that is responsible for the symptoms of the menopause. The action of oestrin in minimal effective doses is to accustom the organism to the new level of hormone activity whereas the administration of unnecessarily high doses inhibits pituitary function and merely postpones the appearance of menopausal symptoms until oestrin therapy is discontinued

**Oestrin Threshold Bleeding**

From the beginning of August to the middle of October, 1936 intermittent uterine haemorrhage was taking place. Observations by Zuckerman (1937) on the cause of uterine haemorrhage in primates have revealed the fact that there are three significant levels of oestrin utilization by the uterus. (The term 'oestrin utilization' is preferred to oestrin concentration, since two factors are concerned—the concentration of oestrin in the blood reaching the endometrium and the degree of sensitivity of the endometrium to oestrin.) These levels are (1) subthreshold, (2) threshold and (3) superthreshold (see Chart II). The superthreshold level is indicated by uterine haemorrhage occurring a week or so after the dose of oestrin is lowered or completely withdrawn. This is known as 'oestrin-withdrawal bleeding'. The threshold level is shown by intermittent bleeding occurring during the period of administration of oestrin—oestrin threshold bleeding."

CHART II—The effect of different levels of oestrin

Zuckerman points out that this type of haemorrhage tends to occur in forty-two-day cycles. The subthreshold level fails to produce bleeding either during or after the period of administration. The haemorrhage which occurred in August could not have been oestrin-withdrawal bleeding, since the daily peroral dose of oestrone had been raised from 25,000 to 30,000 IU (2.5 to 3 mg) a fortnight previously. Nor can the haemorrhage in September be regarded as a withdrawal bleeding, for the dose had been lowered only from 30,000 to 25,000 IU. It seems probable, therefore, that this represents threshold bleeding, and it may be noted that the two main bouts of haemorrhage occurred at an interval of thirty-seven days, which approximates fairly closely to Zuckerman's forty-two day interval. It will be seen that the dose of oestrin required to produce threshold bleeding is about five times higher than that required to relieve subjective symptoms such as hot flushes.

The calibration of the threshold-bleeding level is important, since it provides information as to the physiological dose of oestrin requisite for proliferative development of the endometrium, and consequently suggests the dosage

necessary to stimulate the endometrium in cases of amenorrhoea. An attempt was therefore made to determine the level for threshold bleeding when oestrone was given by injection. Administration of 10 000 IU (1 mg) of oestrone by injection daily for a fortnight induced withdrawal bleeding after a seven day interval. Later (April 1937) a three weeks course of 7 000 IU by injection and a fortnight's course of 6 000 IU gave rise to withdrawal bleedings nine and eight days after administration was discontinued whereas a seven weeks course of 5 000 units by injection did not produce uterine haemorrhage. Thus it would appear that the intramuscular dose of oestrin necessary to produce threshold bleeding in this case is between 6 000 and 5 000 IU (0.6 and 0.5 mg) whereas the oral dose was found to be between 25 000 and 30 000 units suggesting that oestrone is about five times as effective by injection as by mouth. This agrees with the observations on the relief of subjective symptoms (frequency of hot flushes curve)—namely that 5 000 units by mouth and 1 000 units by injection diminished the number of hot flushes.

It is not suggested that 5 000 IU represents the bleeding threshold of all castrated women. It is obvious that this level depends on factors such as the degree of atrophy of the endometrium at the time the experiment is begun and the individual sensitivity of the subject's reproductive tract to oestrin. For instance in the case of another castrate a three weeks course of daily injections of 1 000 IU for fourteen days followed by 2 000 IU for seven days provoked an oestrin withdrawal bleeding five days later whereas a fortnight's course of 1 000 IU daily provoked no withdrawal haemorrhage. Her bleeding threshold would therefore appear to be between 1 000 and 2 000 IU daily.

#### Effect of Implantation of a Tablet of Crystalline Oestrone

Parkes (1938) has recently drawn attention to the fact that the duration of effect of an endocrine preparation is inversely proportional to its solubility in the body fluids. For this reason the administration of oestrone or oestradiol by injection in the form of the monobenzoate prolongs the effect by diminishing the rate of absorption from the site of injection. The pure crystalline hormone administered in solid form and not in an oily solution appears to be absorbed considerably more slowly and Deanesly and Parkes (1937) have shown that the implantation and reimplantation of a single 6 mg tablet of compressed crystalline testosterone into a series of castrated rats for ten day periods demonstrated its effectiveness over a total of 130 days.

This method has been employed in the case under discussion. The hot flushes frequency curve was allowed to reach a plateau at a fairly high level (about ten to twelve a day) and then on January 17 1938 a 14 mg (140 000 IU) tablet of compressed pure crystalline oestrone was placed beneath the skin of the abdominal wall. The hot flushes frequency curve began to descend in about a week and reached a trough at four to six daily about four weeks after implantation after which it gradually rose again reaching a level of eight to ten daily flushes about seven weeks after implantation. Assuming that absorption from the surface of the crystal occurred at a constant rate (though there is no evidence to support this assumption), and taking the period of effectiveness as four to five weeks (twenty eight to thirty five days) it may be calculated that the daily absorption corresponded to 0.4 to 0.5 mg (4 000 to 5 000 IU). An examination of Chart I

shows that the effect of the implantation on the hot flushes-frequency curve is very similar to that of daily injections of 5 000 IU (see February 1937).

The inference is that the dosage used in this case was too low and that the effect might have been more marked and prolonged if a crystal of greater weight had been implanted. Taking these facts into consideration it would appear that this new method of hormone administration represents a significant advance in the field of endocrine therapy.

#### Summary

Experiments performed on a human female castrate are described.

1 Administration of oestrin in quite small doses by mouth was effective in controlling symptoms.

2 The level of oestrone threshold bleeding was found to be between 6 000 and 5 000 IU by injection and 25 000 and 30 000 IU by mouth suggesting a peroral intramuscular ratio of 5 : 1.

3 A 14 mg tablet of crystalline oestrone was implanted subcutaneously and was effective in controlling symptoms for four or five weeks.

I should like to acknowledge my indebtedness to my colleagues in the endocrine clinic Dr A. C. Hampson and Mr H. A. Hamilton for their interest and co-operation in this experiment and to thank Dr A. S. Parkes for supplying me with the tablet of crystalline oestrone. Dr A. N. Macleith of the Organon Laboratories for generous supplies of mentormon and Messrs Paines and Byrne for supplies of oestriol (tridestrin).

G. Crile (*Clev. clin. Quart.* January 1938 p. 33) discusses the diagnosis and treatment of essential hypertension. There is an increase in the diastolic blood pressure changes in the optic disks and in the kidneys and a history of disability and distress. Sclerosis may become established if hypertension begins in early life. It is urged that when hypertension has reached the malignant phase the risk of operation in the hope of curing or relieving the symptoms is justified. In a series of sixty nine consecutive cases symptomatic improvement was noted in 95 per cent on discharge from hospital. Surgical treatment of essential hypertension was carried out on the adrenal sympathetic system in 213 patients; a total of 358 operations being performed. Of these 200 were coeliac ganglionectomies in 129 patients. It was found that this operation with denervation of the adrenal glands gave the most encouraging results. It does not interfere with metabolism or with the function of the digestive or genito-urinary tract. It was found that many patients were completely relieved of symptoms after operation while a large majority experienced considerable relief. Among the last 112 individual coeliac ganglionectomies there have been only two deaths. It was considered that impaired kidney function was a contraindication to the operation but the early results in two cases in which glomerulonephritis was associated with essential hypertension have led the author to believe that this may not be correct. A final judgment regarding the end results of coeliac ganglionectomy cannot yet be made but it is suggested that the symptomatic relief, the improvement in the blood pressure and the fact that many patients are able to return to their usual occupation make this form of operative treatment well worth while.

## LEUCOPENIA IN PNEUMOCOCCAL PERITONITIS TREATED BY SODIUM PENTOSE NUCLEOTIDE

BY

J B G. MUIR, M.B., M.S., F.R.C.S.

*Principal Medical Officer Kailan Mining Administration  
Tongshan North China*

The exceptionally high mortality rate of primary pneumococcal peritonitis (Rischbieth, 1910-11, 90 per cent, McCartney and Fraser, 1921-2, 65 per cent) justifies the evaluation of any ancillary methods of treatment used in surviving cases. There appears to be a general consensus of opinion to-day in favour of delaying operation until there are signs of localization of the abdominal exudate—that is, about the end of the second week of the disease in surviving cases. Horine (1935), quoting Continental surgeons, gives a 75 to 95 per cent mortality rate in cases treated by early operation, compared with up to 25 per cent in cases treated by simple drainage in the stage of localization. From time to time, however, a case occurs where the diagnosis is uncertain, and the surgeon, feeling that he may be overlooking peritonitis of appendicular origin and lacking the courage to temporize, decides to explore the right iliac fossa. In the diagnosis of such cases of peritonitis of doubtful origin much importance has been attached to the leucocyte count as indicating the type of infection present (Budde 1933, Gibson, 1930). It is considered that an unusually high leucocyte count with a high percentage of polymorphonuclear cells is distinctive of pneumococcal peritonitis.

The case about to be described, in which the initial leucocytosis was slight, presented difficulties in diagnosis so far as the origin of the peritonitis was concerned, and the history of the administration of an aperient soon after the onset of the attack was the deciding factor in favour of immediate operation.

At operation the true state of affairs—namely, an "idiopathic" general peritonitis—was disclosed, this was found to be pneumococcal. The subsequent course of the disease, which responded to treatment in a remarkable manner despite the later complication of double basal pneumonia leads me to publish this case, in the hope that the measures adopted may be useful to surgeons faced with a similar condition. For a few days, however, the case appeared to be hopeless, both clinically and especially so far as prognosis could be based on the blood picture.

### Case History

A British girl aged 10 years in good health, was seized with acute generalized abdominal pain on the night of May 22 1937. This became progressively worse during the following morning when she vomited several times. Her mother attributing her symptoms to overindulgence at a recent party administered a dose of salts. The child's condition became worse during the afternoon when her temperature rose to 102°. Several loose motions were passed, and the abdominal pain appeared to be very severe.

I first saw the child at 6.30 p.m. on May 23, and it was obvious that there was general peritonitis. Her pulse was 120, her temperature 102.8° and respirations 24 per minute. Abdominal distension was present and she was in considerable distress from pain most severe over the lower abdomen which was held almost immobile during respiration. A vivid malar flush was evident. On palpation marked

rigidity of the lower abdomen was felt, and although tenderness was general it appeared to be most definite over the right iliac fossa. The patient stated that her pain was worse in that region when the right thigh was fully extended. On rectal examination general tenderness was elicited, but no localized swelling was palpable. There was no history of any vaginal discharge. Examination showed no abnormal signs in the heart or lungs, and urinalysis was normal. A blood count resulted as follows: Red blood cells, 4,980,000 per cmm, white blood cells, 10,600 per cmm, haemoglobin 80 per cent, colour index, 0.81. The differential count read: Polymorphonuclears 80 per cent, large lymphocytes, 2 per cent, small lymphocytes, 17 per cent, hyalines, 1 per cent, eosinophils, nil. Owing to the extremely acute nature of the child's symptoms and the history of the aperient, a diagnosis of acute peritonitis of appendicular origin was made and immediate operation advised. This was performed under ether anaesthesia at 7.45 p.m. on May 23, approximately twenty-two hours after the onset of the patient's symptoms.

The abdomen was opened by Battle's incision, and a small quantity of greenish-yellow seropurulent fluid escaped on incising the peritoneum. Smears and cultures were taken for examination. The coils of small intestine were intensely congested and dark red in colour, with numerous flakes of fibrinous lymph adhering to the serous coat. The appendix was red and congested, as were the pelvic organs, and some purulent fluid was present in Douglas's pouch. Apart from sharring in the general inflammation the tubes did not appear to be particularly inflamed. The case suggested in early streptococcal peritonitis appendectomy was performed, the fluid exudate completely removed by suction and the abdomen closed without drainage. The patient was returned to bed and nursed in the Fowler position a continuous rectal drip saline with 5 per cent glucose being administered. Later the laboratory reported that the smears contained numerous pus cells with Gram positive diplococci, showing evidence of a capsule. On the following day the cultures yielded a pure growth of pneumococci; the patient had therefore been operated on in the early phase of pneumococcal peritonitis. Unfortunately type sera were not available for the treatment of the case. Blood transfusions did not appear to be indicated.

On the day following operation (May 24) the patient's condition was fair: the pulse was 128, temperature 102° and respirations 26. Abdominal distension was considerable, although the passage of the rectal tube resulted in the evacuation of fluid faeces and gas. Morphine was administered hypodermically in 1/12-grain doses whenever the patient became restless, and large hot fomentations were applied, covering the whole abdomen and flanks. The rectal drip was continued at intervals throughout, and only sips of water were given by the mouth.

Next day the patient's general condition was much worse, with a great deal of abdominal pain and distension, and several fluid motions were passed. The pulse was now 135, the temperature 103.5°, and the respirations 32. A blood count at this stage showed a sharp drop in leucocytes to the extent of a marked leucopenia, and the presence of numerous immature forms. Red blood cells, 4,850,000 per cmm, white blood cells, 2,600 per cmm, haemoglobin, 80 per cent, colour index, 0.83. The differential count gave: Polymorphonuclears, 81 per cent, large lymphocytes 5 per cent, small lymphocytes, 12 per cent, hyalines, 2 per cent, eosinophils, nil. The Schilling-Torgau ratio of immature to mature forms of polymorphonuclears was 6.5. From the general and haematological standpoints the prognosis appeared hopeless.

Dr J B Robinson, who confirmed the blood findings with Dr T J Hua saw the patient in consultation that day and suggested immediate treatment with a pentonucleotide preparation so as to try to induce leucocytosis. The preparation sodium pentose nucleotide (Evans, Sons, Lechar and Webb) was available and treatment was at once started, giving 2 ccm intramuscularly twice daily. This dose was gradually increased during the following days until 5 ccm

was being given twice daily by May 30. The white cell counts during this period were as follows: May 27 3-00, May 28 6-600, May 29 1-700, May 30 23-700.

On June 1 as the patient's abdominal condition was assuming a more chronic character a further rise in temperature with dyspnoea and severe cyanosis heralded the onset of pneumonic consolidation in the lower lobes of both lungs (pulse 140, temperature 104, respirations 42). At this time the leucocytes numbered 27,000 but the Schilling-Torgau count gave a 3.6 ratio. During the next week the clinical picture was one of typical pneumonia and the child's condition became very critical. Routine treatment and careful nursing with intranasal oxygen when cyanosis was severe aided her over until resolution by 10.15 started on June 6. The temperature now began to remit and increasing lower abdominal distension suggested localization of the abdominal exudate. On June 10 several ounces of thick yellow pus were discharged from the wound yielding on culture a pure growth of pneumococci. On June 12 under light ether anaesthesia a suprapubic incision was made and 14 oz of thick odourless yellow pus was evacuated with masses of fibrin. A large drain was left in.

The patient thereafter proceeded to a prolonged but steady convalescence. Pockets of pus higher in the abdomen discharged along the drainage track at intervals. Some delay in complete resolution of the pneumonic consolidation at the left base occurred but the right lung cleared up rapidly. She was discharged from hospital on July 20 and subsequently left for England with her family. She had lost 12 lb in weight during her illness but apart from emaciation was convalescing rapidly and had developed a voracious appetite. Dr Hector Cameron to whom the child was referred wrote in October 1937 that she had made great progress, had put on weight, and had regained the look of health.

Graph showing Fall in Leucocytes after Operation and the Development of Leucocytosis following Pentose Nucleotide Injections

#### Commentary

Fraser (1931) has suggested that the peritoneal area as representing a mesothelial space has peculiar properties of reaction in response to general infection. From observation of cases of so-called idiopathic peritonitis—that is cases in which no obvious source of intraperitoneal infec-

tion can be demonstrated—he believes that the peritonitis is in some respects a salutary feature affording possibilities of an immunity influence. On such a basis pneumococcal peritonitis is explained as a local reaction secondary to pneumococcal septicaemia—a condition that was undoubtedly present in this case as proved to be the subsequent development of bilateral basal pneumonia.

Recovery from primary pneumococcal peritonitis is not unusual though the mortality rate is high but recovery in any case of peritonitis where leucopenia and a return to the left mark the immediate post-operative course must be very rare. Piney (1926-7) in his *Arts and Galleries* on the importance of haematology in surgery points out that recovery rarely occurs in these processes where there is a progressive fall in the total number of leucocytes with an extreme degree of shift to the left, total absence of eosinophils and well marked lymphopenia.

In discussing cell counts in the different types of pneumonia however Fleming (1926) has stated that in Type I infection—the usual one in pneumococcal peritonitis—according to Brechot and Nove-Josseland (1931)—high leucocyte counts are common. Low leucocyte counts are found in many patients who recover despite a grave condition at the onset of the disease. He also points out that in young patients recovery may occur with moderately low counts. The remarkable response in the blood picture of this case during the course of sodium pentose nucleotide injections however coincided too closely with clinical improvement to be merely accidental.

Wilkie (1931) has advocated the pre-operative injection of *B. coli* and streptococcal vaccine combined with sodium nucleate as a useful prophylactic against peritonitis in abdominal operations where there is a risk of serious infection. While the pentose nucleotide preparations have been of special value in the treatment of agranulocytic anginas they would appear to have also a definite place in the treatment of acute surgical infections in which neutropenia results from the effect of the circulating toxins on the bone marrow.

H. Brücke (*Zbl. Chir.* February 12, 1913, p. 49) states that congenital local gigantism in which both skeletal and soft parts are concerned may affect from one to four or various combinations of limbs or small zones such as the finger, toe, ear or nose. Macroductivity is no very rare. The distal is more commonly affected than the proximal part of limbs and the right more often than the left side. A familial occurrence is very uncommon. The parts concerned are specially liable to be the site of pigmented naevi, lymphangiomas, lipomata and fibromata. The case is recorded of a man aged 21 mentally subnormal in whom the whole of the left leg was enlarged, the shin and calf showed a large capillary-cavernous tumour and trophic ulceration. Surgical measures—of amputation, osteotomy to shorten the femur and improve secondary static defects such as scoliosis—were it is said unlikely to be successful for the giant parts have generally an interior functional capacity and regenerative power. This patient's trophic ulceration dated from attempts to cure by sclerosing injections the varicose veins of the naevus.

## ECLAMPSIA

### A STATISTICAL REVIEW

BY

**G. GORDON LENNON, M.B., Ch.B.***Obstetrical Officer, St Chad's Hospital, Birmingham, formerly  
Resident Medical Officer, Aberdeen Maternity Hospital*

This is an attempt to observe by statistical study certain features in the behaviour of eclampsia in the north eastern area of Scotland, an area served to a great extent by the Aberdeen Maternity Hospital. A period of five years (1932-6) was chosen so that the number and distribution of the cases would be representative enough for deductions to bear a satisfactory degree of accuracy.

#### Incidence

TABLE I—Incidence of Eclampsia According to Year

Year	Jan 1932	1933	1934	1935	Dec 1936	Total
Total confinements	722	705	759	823	812	3,851
Cases of eclampsia	10	13	14	11	13	61
Deaths	0	3	1	0	2	6

In the period under review 3,851 women were confined in the Aberdeen Maternity Hospital. Sixty one of these had eclampsia (Table I), giving an incidence rate for the hospital of 1.59 per cent. Professor R. W. Johnstone (1932) has stated that "the incidence is usually placed at 1 in 500," and for comparison it is interesting that he found that "the incidence of eclampsia in the years 1923 to 1930 in the Royal Maternity Hospital, Edinburgh, was exactly 2 per cent of all cases delivered in hospital, excluding abortions." Chamanlal Mehta (1936) records that the incidence of eclampsia in his hospital in Bombay for the years 1929 to 1934 was 0.45 per cent. He further states that "the figures of the Rotunda Hospital, Dublin, in 1930 were 0.5 per cent."

Hospital statistics, of course, give an exaggerated idea of the frequency of eclampsia. No account is taken of the great number of what I may term "extramural pregnancies." In this connexion I tried to estimate the true incidence of eclampsia in Aberdeen for one year by getting the total number of births from the registrar, but I found it impossible to arrive at the total number of cases of eclampsia occurring that year which were treated by the patient's own doctor at home or in a nursing home. Douglas and McKinlay (1935a), discussing maternal morbidity and mortality in Scotland, state "In the sample of births discussed 0.19 per cent of the cases were described as having suffered from eclampsia."

#### Seasonal Incidence

TABLE II—Seasonal Incidence of Eclampsia

	Jan	Feb	Mar	Apr	May	June	July	Aug	Sep	Oct	Nov	Dec
Cases of eclampsia	7	4	8	4	5	4	5	2	5	5	6	6
Deaths	1	-	-	-	-	1	1	-	1	-	1	1

It will be seen from Table II that during the months October to March (inclusive) there were thirty-six cases of eclampsia, whereas from April to September (inclusive) there were twenty-five cases—an appreciable difference of eleven cases or 18 per cent. It would appear therefore

that the onset of cold damp weather was one factor favouring an increase in the incidence of eclampsia in this part of Scotland. A somewhat similar finding has been recorded by Hues (1928).

#### Age Incidence

TABLE III—Incidence of Eclampsia According to Age

Age Period	17-20	21-25	26-30	31-35	36-40	41-47
Cases of eclampsia	6	26	8	14	4	3
Deaths	-	-	-	4	-	1

This table is significant in that forty cases (65.5 per cent) occurred up to the age of 30 years, whereas twenty-one cases (34.5 per cent) occurred after that age. But even more obvious is the fact that there was no mortality in the younger group and a very appreciable mortality (28.6 per cent) in those over 30 years of age.

#### Gravidity Incidence

TABLE IV—Incidence in Relation to Number of Pregnancies

	Number of Cases	Incidence	Mortality	
			Number	Per Cent
Primiparae	36	59.02%	2	5.5
Second Pregnancy	9	14.75%	0	0
Others	6	26.23%	4	66.66

It will be seen that 59 per cent of all the cases occurred in primiparae, and that 73.77 per cent occurred in either first or second pregnancies. The much higher mortality in multiparae might be assumed to be due to the existence of some degree of renal disease previous to the pregnancy, a fact I was unable to study accurately. These figures are not much in accord with those for Scotland as a whole. Douglas and McKinlay (1935b) say "The foregoing table shows that 83.5 per cent of all cases occurred in primigravidae, 14 per cent in two gravidae, and under 3 per cent among the higher degrees of multiparity. Among all cases of eclampsia 80 per cent were said to occur in primigravidae."

#### Type Incidence

TABLE V—Incidence in Relation to Labour

	Number of Cases	Mortality	
		Number	Per Cent
Ante partum	31	41 over 30 years of age	12.9
Post partum	26	21 15c	7.7
Both	4	-	-

Twenty of the twenty-six post-partum cases (77 per cent) occurred in women before the age of 30 years, and 65.4 per cent before 25 years of age. Of these post-partum cases 62 per cent were in primiparae. On the other hand, 50 per cent of the ante-partum cases were in women over 30. The point I wish to make from these figures is that the ante-partum and post-partum grouping of cases is artificial and should be discarded. It seems that the younger the woman and the less parous the longer does eclampsia with its latent period take to reach its acme, or the later is its onset and the milder its severity.

I would draw attention to the large proportion of post-partum cases in this series. They account for 42.6 per

cent of all the cases and it would appear that eclampsia in this area of Scotland is generally of a milder type than that seen in other parts of the country. For comparison I quote from Bourne and Williams (1932a). It will be noticed that contrary to the usually accepted belief post partum eclampsia (in London) bears a much higher risk than the other forms. I am disappointed that the age factor was not considered in that review.

### Distribution of Cases

TABLE VI—Town versus County

	Number of Case (1)	Mortality		Ante natal Supervision	
		Number (2)	Per Cent. (3)	Number (4)	Per Cent. (5)
Town	55	7	5.71	15	42.9
County	46	4	15.4	1	3.4

Of the cases of eclampsia 57 per cent were in town patients and 43 per cent in county women. The most striking features of Table VI are Groups (3) and (5) where ante natal supervision was more common the mortality rate was much lower. This is surely a strong point in favour of ante natal care. The above figures are very disappointing to the county. There is of course, no excuse for not carrying out pre natal care. We must recognize the fact however that many of the county cases had to travel between thirty and forty miles in an ambulance in a very ill state before admission to hospital. In this connexion it is interesting to note the distances travelled by those county patients who died. They are: Echt thirteen miles, Peterhead thirty four miles, Peterhead thirty four miles, Alford thirty one miles. This factor of distance is I feel sure an added barrier to recovery in the county patients. One is tempted to remark that these patients should come into hospital at an earlier date by their own choice or conveyance rather than by ambulance as the last resort yet that is the doctor's responsibility. The establishment of rural ante-natal centres would help greatly. Under the new Maternity Services (Scotland) Act 1937 the compulsory examination of the patient by her doctor at least three times before confinement is a progressive step in this direction.

### Illegitimacy

There were ten cases of eclampsia in illegitimate pregnancies—four in county and six in town cases—a total incidence of 16.4 per cent in the series. Of these ten patients two died (both county) giving a mortality rate of 20 per cent—a figure double that for eclampsia in this review as a whole. This point agrees with the following statement (Professor J. M. Munro Kerr (1933a) quoting Kinloch, Stephen and Smith). The death rate among the mothers of illegitimate children for 1918 to 1927 was also like that of their infants fully twice as great as among other mothers—namely 13.2 as against 6.0 per 1000 births. Death from albuminuria and convulsions was also distinctly higher.

### Maternal Mortality

Reference to Tables I to VI shows the relation of mortality to year, season, age, gravidity, labour and distribution respectively. The effect of illegitimacy is seen in the preceding paragraph. It will be noted that there were six deaths in sixty one recorded cases during the five years under review. This gives a total mortality rate of 9.84 per cent which compares favourably with

the figures of other hospitals—for example Hewitt (1933).

Successful in reducing maternal mortality in the Glasgow Royal Maternity Hospital in 109 cases of eclampsia or 9.1 per cent the lowest figure yet attained in this hospital as the type of case received into it is of special severity. Further Munro Kerr (1933b) states. In the Scottish returns there is no evident decline in the death rate from the causes included in this group. The figures are:

Total deaths (1925-30) 591  
Deaths from albuminuria and eclampsia 66 (11.5 per cent)

The Departmental Committee has arranged the deaths investigated as under:

Deaths Percentage Eclampsia 11.6

### Foetal Mortality

There were twenty two children stillborn in the series—a total mortality rate of 36.0 per cent including an early neo natal loss (two cases) the rate is 59.3 per cent. This figure is undoubtedly favoured to a great extent by the large number of post partum cases (42.6 per cent of total) and it is far short of the reported by Bourne and Williams (1926) as follows. The great risk to the foetus of a mother who has chronic nephritis has long been known but in toxæmia it is very much less. Some babies are lost by premature induction of labour at a date too early for their survival while others are born macerated. The total foetal death rate including neo natal loss is from 10 to 15 per cent.

### Treatment

The treatment given to the cases in this review followed very closely that which is employed in the Rotunda Hospital, Dublin (Solomons 1932). Colonic lavage, gastric lavage and venesection where blood pressure is 160 mm Hg or over were performed with the patient well under the influence of morphine. A chart was kept indicating the relation of fluid intake to output per day. Thyroid extract (B.P.) 1 grain every four hours was administered as a diuretic. Veratrine 1/2 ccm intramuscularly was in many cases used as an alternative to venesection.

The obstetric treatment given was induction of labour by rupture of the membranes near to term. When the patient was in labour it was completed as quickly as possible. Conservative measures were employed only if the patient was unduly far from term and if she responded well to treatment.

### Conclusions

1 The incidence rate of eclampsia in the Aberdeen Maternity Hospital over a period of five years (1932-6) was 1.59 per cent.

2 An appreciable difference of 18 per cent was found between the incidence of eclampsia in the winter months, October to March, and that in the summer months, April to September. This would appear to indicate that the onset of cold damp weather was one factor in causing an increase in the incidence of eclampsia in this part of Scotland.

3 73.77 per cent of cases occurred in either the first or second pregnancies.

4 The greater proportion of cases (65.5 per cent) occurred up to the age of 40 years without any difference in the mortality rate or in the severity of the cases. The mortality rate over 40 years of age was 28.6 per cent.

5 Ante partum eclampsia was as common after 30 years of age as before. The post partum type of the disease

hand, was much more common (77 per cent of cases) before the age of 30

6 There was a most striking difference between the mortality rates for the town (5.71 per cent) and the county (15.4 per cent). This was supported by the finding that only 3.84 per cent of county patients, as opposed to 42.9 per cent of town patients, received ante natal supervision

7 The total maternal mortality rate for this series was 9.84 per cent. This figure was doubled in illegitimate pregnancies

8 The foetal mortality rate, including neo-natal loss, was 39.34 per cent

I wish to record my thanks to the staff of Aberdeen Maternity Hospital for putting case-records at my disposal and to Professor Baird for his helpful suggestions

## SPONTANEOUS HAEMATOMYELIA

BY

J. McDONALD HOLMES, M.D., M.R.C.P.

Physician, Staffordshire General Infirmary

Haematomyelia occurring without any history of injury in otherwise healthy subjects is very rare, and references to it in the literature are scanty. In a larger number of cases a history of slight direct or indirect injury to the spine is obtained, and although in many of them the injury may seem negligible in comparison with the severity of the symptoms, it is not justifiable to include these with the cases of truly spontaneous haematomyelia.

#### Cases in the Literature

C. Doerr (1906-7) was able to collect only sixty-three cases in his full review of the condition, which comprised all the literature from 1808 to 1904. In thirty-three of these cases no aetiological factors were mentioned, and of the remainder a convincing explanation in the light of modern pathology was available in only three cases. One was said to be due to syphilis, and in another military aneurysms of the cord were found at necropsy. In the third case the haematomyelia followed an earlier apoplexy in a man aged 70. J. Lepine (1900), in a review of forty-five cases suggested that in many instances 'fragility' of the spinal blood vessels was present, apart from such vascular abnormalities as aneurysm or arteriosclerosis, but he is cautious in his conclusions, and makes no definite suggestions as to the nature of the fragility. Chevallier and Desoille (1930) discuss six cases of spontaneous haematomyelia in young subjects, five of which came to necropsy. In three of them aneurysmal dilatations of the

vessels of the cord were found (one is also included in the reviews of Doerr and of Lepine—that of Liouville, *Soc. de Biologie*, 1872). Of the other two cases one was in a child, aged 2, in whom an endarteritis with thrombosis of the spinal vessels was found, probably due to syphilis. The remaining case showed a generalized hyaline degeneration of the arteries of the central nervous system. Chevallier and Desoille suggest that the most frequent cause of spontaneous haematomyelia in young subjects is congenital syphilis, but apart from the child aged 2 none of the cases they discuss affords very convincing evidence of syphilitic infection. On the available evidence it seems more reasonable to follow the suggestion of Lepine and suppose that a vascular fragility in the nature of a congenital haemangioma or aneurysm is responsible for the majority of cases, at any rate in young subjects in whom there is no evidence of systemic or arterial disease. In Doerr's sixty-three cases the incidence is much higher in young subjects than in old ones, as will be seen from the following figures:

Age	0-10	1 case	Age	41-50	4 cases
	11-20	11 cases		51-60	2
	21-30	22		61-70	6
	31-40	12			

In five cases the age was not given, but 79 per cent of the above occurred under the age of 40, and, so far as can be made out from the review, most of the subjects had previously been healthy.

Haemangiomatic malformations of the spinal vessels occasionally give rise to symptoms of spinal compression, and they are not uncommonly encountered in neurosurgical clinics when laminectomy is performed. Spontaneous rupture of these haemangiomas is, however, a very rare occurrence. Cases have been recorded by Ohlmacher (1899), Lissowsky (1933), Buckley (1936), and Richardson (1937), the clinical features of which resembled the one recorded below, and in which the haemangioma was definitely demonstrated at necropsy. Richardson also describes a case due to syphilitic endarteritis of the spinal vessels.

Aneurysms of the spinal vessels are very rare, but they have been described in association with contraction of the aorta, and are occasionally found in syphilis and periarteritis nodosa. In comparison with the congenital "berry" aneurysms of the circle of Willis they are practically unknown.

#### The Clinical Syndrome of Spontaneous Haematomyelia

The onset of paraplegia is nearly always sudden, and paralysis is usually complete within a few minutes. It may accompany a slight exertion, but often there is no history of this. Severe lancinating pain, often of a 'girdle' distribution, occurs at and above the level of the lesion, and there is a more or less complete loss of sensation below the level of the haemorrhage, depending upon its size. The pain persists for several days afterwards, and if the haemorrhage extends may change in level and severity.

Apart from injury there is probably no lesion of the cord in which the symptoms develop as suddenly as in haematomyelia. In Doerr's collection of sixty-three cases the onset was sudden in fifty-five, and pain was a prominent feature in thirty-six. The paraplegia is flaccid at first, and the deep reflexes are usually lost owing to the 'spinal shock' but an extensor plantar response may sometimes be obtained. In the case to be described the plantar responses remained flexor for a considerable time.

The haemorrhage usually occurs into the central grey matter of the cord and the sensory changes may resemble those of syringomyelia in cases where the haemorrhage does not extend into the lateral and posterior columns but it is more common to find a very extensive loss of all forms of sensation in the early stages owing to the spinal shock and oedema. Sphincter control is generally lost and there is complete retention of urine and faeces.

Considerable improvement occurs in patients who survive the initial stages. The spinal shock wears off and the oedema of the cord subsides with a gradual return of sensation and motor power. In favourable cases there may be little residue beyond a segmental band of anaesthesia but if the white matter of the lateral and posterior columns has been damaged there will be a much more extensive sensory loss with spastic paraplegia and perhaps permanent loss of sphincter control. If the grey matter of the anterior horns is damaged muscular atrophies are a sequel. Death in the early stages is usually due to respiratory paralysis as a result of the upward extension of the haemorrhage involving the cervical cord and origin of the phrenic nerves. It may occur later from urinary or other sepsis complicating the paraplegia.

The case described below presents most of the typical features of spontaneous haematomyelia. Death from respiratory paralysis was averted by the use of a Drinker's respirator and the symptoms were considerably relieved by repeated lumbar puncture.

#### Case Record

A girl aged 15 was sent into the Staffordshire General Infirmary on March 19 1937 by Dr McGeough. The evening before admission she was engaged in household duties when she was seized with sudden severe pain in the back and legs. The legs rapidly became weak and she had to sit down. Soon afterwards she found that her legs were completely paralysed and numb and she was unable to pass urine. The site of greatest intensity of the pain was in the mid-dorsal region and it had a lancinating character like knife stabs shooting round to the front of the chest and abdomen.

On admission to hospital there was a complete flaccid paraplegia with loss of all sensation except deep pressure up to the fifth dorsal level. Immediately above this there was a narrow zone of hyperaesthesia above that sensation was normal. The left pupil was larger than the right but both reacted normally to light and accommodation. The cranial nerves showed no abnormality. The abdominal reflexes and all the tendon reflexes of the lower limbs were absent but the plantar responses were present and were flexor. There was complete retention of urine and the bladder was distended up to the umbilical level. No history of any recent or previous illness or of any injury or undue exertion could be obtained and before the onset of paralysis there had not been even slight symptoms referable to the nervous system. Radiographs of the dorsal and lumbar vertebral column showed no abnormality.

On the first day in hospital lumbar puncture revealed a deeply blood stained fluid under a pressure of 290 mm. There was no spinal block. The protein content of the fluid was 360 mg per 100 c.c. and the supernatant fluid was not yellow in the first specimen. The Wassermann reaction was negative in the blood and the cerebrospinal fluid. On the second day the pain in the back was still severe and the cerebrospinal fluid was still deeply blood stained and under a pressure of 220 mm. On the third day the amount of blood in the cerebrospinal fluid was less and the pressure had fallen to 200 mm but the level of sensory loss was found to be rising and some respiratory distress became evident.

On the fourth day there was complete loss of all forms of sensation below the second dorsal level with severe headache and neck rigidity suggesting that blood had reached the posterior fossa. Respiratory distress and cyanosis were much

more evident and movements of both chest wall and diaphragm were feeble. The cerebrospinal fluid pressure had fallen to 1.0 mm and the blood content was very much less. The patient was put in a Drinker's respirator and artificial respiration was kept up almost continuously for the next ten days when it was found that the sensory level had descended to the fifth dorsal segment and breathing was possible without distress or cyanosis. The cerebrospinal fluid was then slightly blood stained and yellow and was under a pressure of 120 mm. The paraplegia and complete sensory loss continued for many weeks. Some automatic bladder function appeared after about the fourth week but up to that time there was complete retention. There was likewise retention of faeces and rectal washouts had to be given.

By May 12 a good deal of recovery had taken place and the upper limit of sensory loss had descended to the ninth dorsal segment. Deep pressure and vibration sense were present below this level and pin prick and light touch could be felt but they gave rise to unpleasant sensations of the thalamic type. Temperature discrimination was poor. There was a constant feeling of pins and needles in the lower legs. Some motor power had returned to the right leg and flexion and extension of both ankles could be performed and the right knee could be flexed and extended. Both legs were very spastic and the tendon reflexes were grossly exaggerated. Knee and ankle clonus were easily started. The plantar responses had become extensor. No sphincter control had yet returned. The cerebrospinal fluid was normal.

The patient was seen again on February 12 1938. She is now able to walk although with difficulty. Both legs are very spastic with bilateral extensor responses and knee and ankle clonus. There is no appreciable impairment of any type of sensation even of segmental character and there is only an occasional slight impairment of voluntary control of the bladder. Apart from her spastic paraplegia no patient perfectly well.

The most probable explanation of the aetiology in this case is spontaneous rupture of a spinal haemangioma and from the evidence which can be obtained from the available literature it is reasonable to suppose that most cases of spontaneous haematomyelia in young subjects are due to this cause. It is possible that a few cases may be due to rupture of aneurysms but aneurysms of the spinal vessels unlike those of cerebral vessels are very rarely encountered either in the post mortem room or at operation. In older subjects syphilis or the spinal disease may be a factor in determining their rupture but there is little evidence that it is of common occurrence.

The first congress of the International Society of Comparative Biology will be held at Nice from June 2 to 6 (Whitson 2c). This congress was brought into being by the Medical Society of Climatologists and Health of the Mediterranean Coast with the aid of the International Association for the Study of Solar, Terrestrial and Cosmic Radiations. On June 4 and 5 the meetings will be continued in Monaco. There will be various scientific and social excursions during the congress the programme of which includes discussions on ultraviolet light, conductivity and ionization of the air and their effects on human beings, and the value of climatology in medicine and botany. Requests for a detailed programme should be addressed to the President of the Medical Society of the Mediterranean Coast Dr M. Floure Rue Verdi 24 Nice. At the end of the congress there will be an excursion to Corsica.

## Clinical Memoranda

### Intra-nasal Ionization for Hay Fever

A special clinic for the treatment of hay fever by intra-nasal zinc ionization, under my care, was organized in 1937 at the Chest Hospital, Margaret Street, W1. Owing to the publicity given to this method, and to the successful results obtained by many who had used it, a large number of patients attended. In order to assess the value of this treatment, all those treated were asked to reply to a questionnaire.

#### A STATISTICAL SURVEY

Between March and July 860 cases were treated. There were 659 replies to the questionnaire. Of those replying 20 had only one treatment and therefore will not be included in this statistical survey. The figures are therefore based on 639 adequately treated cases. Of these 639 cases 80 per cent were benefited by the treatment—namely, 9 per cent were free of all symptoms during the season, 35 per cent were greatly improved, and 46 per cent were moderately relieved.

The age incidence of the patients who came for treatment was as follows. The majority—namely, 63 per cent—were between the ages of 20 and 40 years, 20 per cent were between the ages of 40 and 60 years, 13 per cent were between the ages of 10 and 20 years, 3 per cent were over 60 years, less than 1 per cent were under the age of 10.

The statistical review reveals some interesting facts—for example although the hay fever was shown to begin under the age of 10 in 23 per cent of cases, only less than 1 per cent of patients under that age actually came to the clinic for treatment. Similarly, although in 40 per cent of cases the age of onset was between 10 and 20 years only 13 per cent of patients of that age attended the clinic for treatment. Between the ages of 20 and 40 years the proportion of patients who came for treatment was more than double the corresponding figure for the age at onset—that is whereas the symptoms were shown to begin between the ages of 20 and 40 years in 30 per cent of cases, 63 per cent of the patients treated were of that age. These figures may indicate either that the younger patients are less concerned by the symptoms, or have not the time, inclination, or material means to undertake a course of treatment.

The sexes were represented more or less equally—that is, 55 per cent male, 45 per cent female. In over 50 per cent of the cases there was a definite familial predisposition.

Slightly more than half the patients had symptoms over two months during each season. Of the remainder, the average duration of the symptoms was four to six weeks.

#### COMMENTARY

This survey has proved that impressions based on a limited experience may be fallacious. Until last year, under the impression based on a previous experience of twelve years with a limited number of cases, I recommended a pre-seasonal treatment, whereas the statistics of a much more extensive number of cases have shown that the fullest benefit is obtained when treatment is given either immediately prior to the onset or during the attack. Equally fallacious was the previously recommended strength of the ionization current—between 3 and 5 milliamperes—which I suggested in an earlier article in this *Journal*. At the clinic the best results have been obtained with patients who were treated with a current of 7 to 10 milliamperes.

The number of treatments required and the interval between treatments should vary with each case. Four treatments at weekly intervals are usually adequate, but in

many cases it may be necessary to increase the number of treatments. Where asthma supervened during the latter part of the hay fever season it was found that if the treatment for the rhinorrhoea was successful the asthma was generally relieved.

As so many patients had severe ocular symptoms an attempt was made to relieve this by ionization applied directly to the eyelids. A pad of lint saturated in a 1 per cent solution of zinc sulphate was applied to the eyelid by means of a metal electrode connected to the positive pole, the negative pole being applied to the nape of the neck. A current of 15 milliamperes was given for fifteen minutes. The results of the treatment were so satisfactory that this will be used as a routine treatment during the coming season in all cases with severe ocular irritation.

The numerous applications for treatment during the last hay fever season necessitated the creation of a special organization to deal with the large number of patients. I am indebted to our radiologist and electrotherapist Dr Orley who made it possible to treat a large number of patients simultaneously. The medical assistants were concerned only with the picking and unpacking of the nose. Thus each assistant was able to deal with fifteen to twenty patients in an hour. The actual ionization was supervised and carried out by experienced nurses, each in charge of six to eight ionization sets, so that each nurse was able to deal with twenty-five to thirty cases in an hour.

#### CONCLUSIONS

(1) Ionization treatment is definitely beneficial in a large proportion of hay fever cases.

(2) The best results are obtained by treatment given just before or at the onset of the symptoms.

(3) The strength of the current should vary between 6 and 10 milliamperes, the weaker current having proved less effective.

(4) Zinc ionization of the conjunctiva may prove to be of considerable benefit in cases of severe ocular irritation.

Laryngologist, Margaret Street  
Chest Hospital, W1

### Hernia through the Right Dome of the Diaphragm

The following is a report of the case of a planter aged 28 years who was referred to hospital by two doctors with a diagnosis of chronic appendicitis. He gave a typical history of pain around the umbilicus and in the right iliac fossa. He had repeated attacks of this pain, each accompanied by a slight rise of temperature.

#### CASE RECORD

About two years ago while the patient was in England he suffered from indefinite pains in the loins. He had a series of x-ray examinations which proved negative for renal calculus. A year ago he had a cough which was rather slow in clearing up. His chest was examined radiologically, and his lungs were pronounced to be fairly normal except for a high diaphragm on the right side, the case was diagnosed as pleurisy. Apart from these two mild illnesses the patient had never suffered from any ailment worthy of note except that he sometimes complained of vague gas pains on rising in the morning. These were more marked when he was constipated.

*Examination*—There was slight tenderness in the right iliac fossa. An indefinite mass which did not move on respiration was felt passing across the abdomen at the level of the umbilicus. Permission was obtained from the patient to perform a laparotomy instead of the usual McBurney's incision. Undue dullness was present over the right lower

lobe of the lung. The heart was normal as were the temperature pulse and respiration rates.

**Operation**—The abdomen was opened through a low right paramedian incision. The liver presented in the upper part of the wound. The appendix could not be traced and the incision was enlarged. The liver was displaced downwards and the lower edge was lying below the umbilicus. It was retracted upwards and the following organs were seen: (1) Large intestine twelve to fourteen inches in length commencing on the right side of the pelvis proceeding upwards and to the left being finally invaginated into the peritoneum at the level of the body of the second lumbar vertebra and slightly on the left side. The mesenteric attachment of this visible portion of the large intestine allowed it moderate mobility. No small intestines were visible in the general peritoneal cavity. (2) The stomach which was normal in appearance. The first portion of the duodenum passed sharply backwards and was lost behind the liver. (3) The liver which was low in position and very movable. (4) The gall bladder which was normal in appearance and in position relative to the liver. (5) A knuckle of intestine which was felt and seen retroperitoneally behind the liver. The abdomen was closed.

Three weeks after the operation the patient was submitted to a thorough radiological examination. The first barium meal was given at 3 a.m. the second meal was given and the first x-ray film taken at 9 a.m. Other films were taken at later intervals. These showed the intestines protruding through an opening in the right diaphragm near the mid line and withdrawing as they became empty. The appendix is well outlined and is apparently not diseased. All the small and the majority of the large intestines are contained in a peritoneal diverticulum above the liver. Screening showed the right diaphragm in an unusually high position but capable of movement. The passage of the barium from the stomach along the coils of the small intestines was unusually rapid.

#### CONCLUSIONS

We wish to draw attention to several unusual points in this case:

1 The vague symptoms which did not give any suggestion of diaphragmatic hernia except vague gas pains. The definite and repeated reference of the pain to the right iliac fossa.

2 The occurrence of a hernia through the right dome of the diaphragm very few cases of which have been reported.

3 A degree of malrotation of the gut which permitted the whole of the small and the greater portion of the large intestines to be contained in the lesser sac of the peritoneum.

4 In spite of the gross degree of rotation of the intestines and presence of the hernia the patient lives a very active life.

Our thanks are due to Major T. J. Hallinan CBE MB BS Director of Medical Services for Jamaica for permission to publish this case and to Dr C. Parkin and his department for invaluable assistance rendered in connexion with the x-ray examination.

The seventh International Congress of Genetics will meet in Edinburgh in 1939 probably from August 23 to 30. The organizing committee have chosen as president of the congress Dr N. I. Vavilov, vice president of the Lenin Academy of Agricultural Science and director of the Institute of Plant Industry, Leningrad and of the Institute of Genetics of the Academy of Sciences of the U.S.S.R. The secretary general is Professor F. A. E. Crew of the Institute of Animal Genetics, West Mains Road, Edinburgh 9.

## Reviews

### TWO CONSOLIDATION ACTS

*The Public Health Acts Annotated with Appendices containing the various Incorporated Statutes and Orders of the Minister of Health etc.* Eleventh edition in four volumes. Volume I. By Sir Joshua Schofield Esquire. Simes M.A. Charles E. Schofield and A. N. C. Shelley M.A. BCL. (Pp. 1426 to be published in four volumes £16 16s. On thin paper 2s. 6d. per volume extra.) London: Butterworth and Company Ltd. and Shaw and Sons Ltd. 1937.

*The Public Health Act 1936*. By H. Samuels M.A. and Philip Fores M.A. LL.B. assisted by Dennis Pugh B.A. (Pp. 570 50s.) London: Sir Isaac Pitman and Sons Ltd. 1938.

It is over sixty years since Lumley's *Public Health* first saw the light. The tenth edition was published in 1930. An eleventh edition, the first volume of which has now been issued, was as the editors explain in their preface, "the work clearly inevitable when it became known that there was a purpose to consolidate the accumulated mass of legislation on local government and public health." While it would doubtless have been formally correct to postpone action until a time when it would be possible to survey the new consolidated fabric as a completed whole, nevertheless it was felt that procedure of that kind would ill serve the needs of many users of the book who would desire its early guidance upon the Public Health Act 1936 which was due to come into operation on October 1, 1937. It was accordingly decided that the first volume of the new edition should contain this important Act accompanied only by the Local Government Act 1933, the former supplying the action of the piece and the latter setting out the stage. These two Acts, together with the annotations upon them, make up a volume of such ample size that it has not been found practicable to present comparative tables showing the extent of the numerous repeals.

In Section 101 of the new Public Health Act, which relates to the smoke nuisance, the source of the smoke is no longer as in the Act of 1875, "an open fire or furnace" but "any installation for the combustion of fuel." It is explained in the annotation to the section that the present phrase is substituted on account of the extension in the Act of the expression "smoke" to include grit and gritty particles, the mechanism for the disposal of which does not usually form part of a furnace. Section 155 of the new Act is of historic interest, inasmuch as it enshrines the proceedings set forth in an adoptive section in the Public Health Acts (Amendment) Act of 1907 for preventing the transmission of a notifiable disease by a book belonging to a public or circulating library. The definition of a drain in Section 243 is described in the annotation as simpler and less restricted than that in the Act of 1875 which had been an enigma to many. The definition of sewer on the other hand has been narrowed down and would, according to the annotation, presumably no longer include the drainage of the fens of Lincolnshire by means of canals. The diseases defined as notifiable are as in the Infectious Diseases (Notification) Act with the omission of continued and sporadic fever. The reasons ascribed in the annotation as to the effect that the former is an obsolete term and that sporadic pyrexia which includes the latter is notifiable by regulation. Among sections of medical interest in the Local Government Act 1933 are those dealing with the appointment and status of medical officers of health.

The volume is excellent in form and admirably produced throughout, as befits a classic.

*The Public Health Act, 1936* by Messrs Samuels and Fores, is a full exposition of the statute, the 347 sections being taken up serially and annotated. In preparing this large work the authors have had it principally in view to provide for the needs of their fellow-members of the legal profession in both its branches and of those who have to administer the Act. As, however, a knowledge of public health law is necessary to many others besides local government officials and lawyers, the book should be useful also to architects, surveyors, builders, public works contractors, and members of local authorities, as well as to medical officers of health and other members of the medical profession who are actively engaged in combating disease or insanitary conditions or promoting child welfare. The introductory pages include a comparative table showing by what provisions in the Public Health Acts, 1936 and 1937, the principal enactments thereby repealed are reproduced.

### PROCTOLOGY

*The Principles and Practice of Rectal Surgery* By William B. Gabriel, M.S. F.R.C.S. Second edition (Pp 364, 9 coloured plates, 162 figures 28s net) London: H. K. Lewis and Co. Ltd. 1937.

The second edition of Mr Gabriel's book is, like its predecessor, a valuable contribution to proctology. The work is based on the well-established teachings of St Mark's Hospital, and the new edition has been thoroughly revised and brought up to date, with the addition of several new chapters on surgical anatomy, injuries of the rectum, and sarcoma of the rectum. The introductory chapter on surgical anatomy includes a description of the ano-rectal musculature which gives the reader a clear and practical conception of the principles and treatment of many of the minor ano-rectal conditions, especially fistula in ano. The important details in diagnosis, preparation, treatment, and after-treatment are plainly presented, and the need for careful attention to these details is stressed and discussed. The illustrations throughout the book are excellent. The chapter on carcinoma of the rectum is outstanding, more especially with regard to spread and prognosis. The details of the operation of one-stage perineo-abdominal excision and the after-treatment are lucidly described.

This book, which is devoid of tiresome repetition and unpadding with useless and confusing text, can be strongly recommended to students, general practitioners, and surgeons as a sound practical guide to the surgery of the rectum.

### STUDY OF THE SKELETON

*Dixon's Manual of Human Osteology* Revised by E. B. Jamieson, M.D. Second edition (Pp 465, 180 figures 21s net) London: Humphrey Milford, Oxford University Press. 1937.

The second edition of this book, revised by Dr E. B. Jamieson, is an excellent memento of the late Professor Francis Dixon and one of the best testaments of his devotion to the descriptive aspect of anatomy. Written in a clear and attractive manner, with the use of the Anglo-Saxon equivalents of the Latin or Greek anatomical terms and in conformity throughout with the B.R., or Birmingham Revision nomenclature, it is certain to meet with a favourable reception. Dr Jamieson has rendered a signal service in bringing about this change in nomenclature which was much desired by the original author

and will greatly facilitate the use of the book by junior medical students, and he has accomplished the change without any material departure from the primary scheme and the easy fluent style of his predecessor. Where in conformity with recent advances in knowledge and requirements of the medical curriculum changes have been deemed necessary, certain sections have been rewritten or simplified and new illustrations, including some excellent x-ray photographs, have been introduced. Certain points in the anatomy of the soft parts have also been included, such as the relation of ligaments to bones (Dr R. Walmsley) and some general relations of the skeleton to the thoracic and abdominal viscera, which are best learned when a student is studying the bones for the first time with the help of a living model or by palpation on his own body.

In general we should like to have seen more references than are already made to applied anatomy—for example, some allusions to the diagnosis and effects of fractures and dislocations of bones, which can well be introduced at the stage when a student is first studying the bones and greatly add to the interest of his work. It is, however, a matter on which there is a difference of opinion as to the period of study in which this information should be imparted, but there are many who think the sooner the better, though they are well aware of the practical difficulties which hinder the insertion of such matter in the way of paragraphs containing "tittbits" of information in small print or in the form of footnotes. One other item which would have been very helpful is some good illustrations showing the microscopic structure of developing bone and some reference to the biochemistry of bone formation, in view of the importance of this knowledge in relation to the proper treatment of certain diseases, defects in the growth of bone, and the union of fractured bones.

The work, considered as a whole, is excellent, and it should serve not only as an introduction to the study of the skeleton but as a most valuable book of reference.

### PROGRESS IN PATHOLOGY

*Recent Advances in Pathology* By Geoffrey Hadfield, M.D. F.R.C.P. and Lawrence P. Garrod, M.D. F.R.C.P. Third edition (Pp 420, 65 figures 15s) London: J. and A. Churchill, Ltd. 1938.

The third edition of *Recent Advances in Pathology* by Professors Hadfield and Garrod, maintains the high standard of the former editions published respectively four and six years ago. The authors have adhered to their main purpose to present recently acquired knowledge of disease processes in a form useful to the student of medicine. And by student it is obvious they have had in mind the unqualified student. Bacteriology and haematology have been dealt with in other volumes of the series so that the pathology consists largely of morbid anatomy, histology, and some pathological physiology. The first chapter is new, and deals with the localization of infection and the nature and significance of bacterial allergy. The sections describing the pathology of rheumatic fever, lobar pneumonia, and glomerular nephritis have been rewritten and brought into line with the principles expounded in the first chapter. The other entirely new chapter is the third, here the potentialities of undifferentiated mesenchyme are described. The chapters on experimental cancer research have been largely rewritten, and they now include sections on chemical carcinogenesis and hereditary predisposition, and they conclude with a review of the present position of the cancer problem as a whole. The authors do not accept the 'virus theory'

of the cause of cancer in general and suggest as a working hypothesis that malignant disease is not aetiologicaly a single entity at all but a type of reaction to a variety of stimuli usually chemical and possibly sometimes microbic

The main skeleton of the book has been retained but every chapter and most sections show evidence of careful revision. To make room for the new material two chapters and five sections on subsidiary subjects and a good deal of introductory matter have been omitted. In the next edition the authors might consider so re-grouping the chapters that the deficiency diseases pernicious anaemia and the ductless glands come together. By setting their own bounds the authors have to some extent simplified their difficult task of selection and with the needs of students in mind they have retained enough introductory and explanatory matter to stress the importance of the new knowledge and to put it in its proper perspective.

It is an axiom of good teaching that the instruction should be clear, connected and as definite as possible. It is better to have a definite wrong view than a muddled one that may be right. The only serious criticism of this book is that the authors have inserted too many contradictory opinions and hypotheses without giving sufficient indication to the student which of them he should believe. The book is complementary to the textbooks of pathology; it still keeps ahead of them and serves the very useful purpose of emphasizing activity in pathology and advance in pathological knowledge.

### FITTING PEARSONIAN CURVES

*Frequency Curves and Correlation.* By W. Palin Elderton. CBE, FIA, FFA. Third edition. Pp. 271. 6 tables. 12s. 6d. net. Cambridge University Press, 1938.

We have received a copy of the new edition of Sir William Elderton's *Frequency Curves and Correlation* now published by the Cambridge University Press. The first edition of the book was a slender volume written more than thirty years ago by a young actuary under the spell of Karl Pearson's genius and hoping to interest his professional colleagues in Pearson's methods. Subsequent editions have corrected errors and incorporated improvements and extensions of the Pearsonian family of curves but follow closely the original plan. As a guide to the fitting of Pearsonian curves to statistical data the book has neither superior nor equal. The examples chosen are actuarial and the mathematical proofs of the several formulae require more knowledge of algebra than most medical readers have. But actuarial terms are clearly defined and the arithmetic of the fittings is given in such careful detail that an intelligent person who knows nothing of actuarial work and little of algebra can use the book without embarrassment. Curve fitting occupies more than half the book; the remainder deals with correlation, sampling errors and goodness of fit. Here the author competes with many writers; he is always lucid and all he says bears the stamp of wide practical experience. This section however has not the unique value of the first part. No doubt some statisticians of repute now deprecate the amount of energy devoted to fitting Pearsonian curves but those who are primarily interested in graduation—that is in the replacement of irregularities due to unsystematic errors or imperfections by a regular curve or function which can be systematically computed and does as little violence as possible to the data—will reply that no better system than Pearson's has been found.

### Notes on Books

*Myocarditis.* The St. Cyres Memorial Lectures is published by Eyre and Spottiswoode at 10s. 6d. In this book six lectures given at the National Hospital for Diseases of the Heart are reprinted. The Lectureship was founded and endowed in 1926 by the late Dorothy Viscountess St. Cyres the lecture to be given annually on myocarditis. This term was used at the time of the foundation of the lectureship to cover both inflammatory and ischaemic disease of the myocardium though to day the tendency is to reserve it for the former. However the lectures deal with both aspects though myocardial ischaemia is as one would expect the main theme. Some of these lectures were delivered several years ago and since the concern a subject which has lately developed very rapidly it is inevitable that they will be found in some respects to be out of date. One lecture on beriberi heart is perhaps of greater interest now than at the time of its delivery since it has recently been claimed that the disease is not confined to the Orient and may occur in the West, particularly in alcoholics. The hypothesis suggested to account for the cardiac condition is however challenged by more recent work.

The longer one lives the more one wonders at the vast amount of specialized knowledge which nurses nowadays are expected to acquire. From the available literature it would appear that an even higher standard is sought in the United States of America than in this country but this supposition is not backed by any positive knowledge on the writer's part. A question one would like to ask is: How many nurses in point of fact are there with their heads crammed with all this theoretical knowledge and how did the comparatively numerous other type whom one comes across not so infrequently ever manage to get their certificates for registration? These thoughts were prompted by a survey of *A Text Book of Surgical Nursing* by Dr. HENRY S. BROOKES (Kington 12s. 6d.). It seems to us after reading this book that it would carry most medical students through their final surgery examination. It is full of detail and the illustrations are excellent.

Mr. H. ST. JOHN RUMSEY, speech therapist and lecturer in speech therapy at Guy's Hospital has written a useful small book on *Clear Speech for Stage, Platform and Pulpit* (Frederick Muller 3s. 6d.). His exact purpose is important. He thus states it: 'Clear speaking by lecturers and public speakers on the platform stage and in the pulpit is rapidly becoming a lost art at the same time the elocution business is booming. This little book is intended to explain the difference between teaching recitations to children and the art of clear speaking to men and women between elocution and speech training. The aims of a good speaker should be three: to be heard to be understood to be remembered. This threefold standard is kept in mind throughout and the author's explanations, instructions and suggestions are not only practical as resulting from large experience but simple, concise and clear. It is possible to differ from him with regard to an occasional detail—as when he advocates the total abandonment of aspiration in pronouncing 'th' or seems to approve the introduction of an 'r' sound in the most open vowels—for example 'ar' for 'ah'—but if all who have to speak in public were to follow broadly his teaching life would be happier both for them and for those who have to listen.

After an interval of nearly twelve years a new edition has been published by the Oxford University Press of *Histological Technique* by H. M. CARLETON, with whose name appears that of E. H. LEACH as joint author. The methods of examination described are for normal tissues, morbid changes and the identification of parasites. We noticed the first edition very favourably on October 2, 1926. The price of this useful book is 1s. 6d.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY APRIL 30 1938

## VIRUS IMMUNITY

Some forty years ago Beclere, Chambon, and Menard<sup>1</sup> passively immunized heifers against vaccinia virus by the injection of serum from immunized animals and gave the first convincing proof that antibodies played a part in the mechanism of immunity to a virus. And although from time to time since then attempts have been made to minimize or deny the importance of antibodies in virus immunity, the great mass of evidence collected since the experiment of Beclere and his colleagues has stressed the importance of the humoral factor. In the case of specific resistance to bacterial infection we have a fairly clear idea of the way antibodies help to ensure the immune state. Neutralization of soluble toxins, the preparation of the bacteria for phagocytosis and intracellular destruction, or more rarely for extracellular lysis, are some of the functions of bacterial antisera which are recognized and have been extensively studied. What part does antibody play in preventing infection by a virus? In order to understand this it is necessary to bear in mind certain differences that exist between this class of infecting agent and bacteria. Apart from their smaller size viruses differ from bacteria in their cultural requirements, they are unable to multiply apart from living cells and appear to be highly specialized intracellular parasites. Some might object to the use of the term "parasite" in connexion with viruses, particularly in view of the recent work of Stanley in America and Bawden and Pirie in this country, which demonstrates to the satisfaction of most workers that some plant viruses are heavy proteins which can be obtained in a para-crystalline form. But both plant and animal viruses behave in many essential ways like living things, and, as Burnet, Keogh, and Lush<sup>2</sup> point out in their recent monograph on the immunity reactions of viruses, they can be most usefully considered as minute, organized, living micro organisms—at all events so far as the problems of immunity are concerned.

There is as yet no evidence that viruses elaborate soluble toxins, as do some bacteria, so that any antitoxic action on the part of antiviral sera does

not come into the picture. Does the antiserum prepare the virus for phagocytosis and intracellular destruction or does it so change the virus that it cannot enter the susceptible cells or multiply if it gets inside them? Beclere and his collaborators<sup>3</sup> expressed themselves in doubt as to whether the specific antibody had a direct virucidal action or whether it altered the tissue cells, rendering them resistant to infection. Quite recently Sabin<sup>4</sup> has supported the latter contention. There is no reason to suppose that the protective antibody has any direct virucidal action, and, as Bedson<sup>5</sup> has pointed out, there is as yet no convincing evidence that virus is sensitized for destruction by phagocytes or by complement. Burnet and his colleagues are satisfied, as others before them, that union between virus and protective antibody does take place, but all are agreed that this union is readily reversible, although prolonged contact may lead to its becoming firmer. In the light of our present knowledge—or lack of it—one can suppose, as Burnet and his colleagues do, that as the result of this union with antibody the virus is hindered from entering susceptible cells or from multiplying should it succeed in reaching that intracellular environment essential to its growth.

So far as the reactions of the viruses and their antisera *in vitro* are concerned there is ample evidence that these differ in no fundamental way from what has been found in the case of bacteria or any other antigen-antibody system. Apparent differences, as Merrill<sup>6</sup> has shown, are due to the small size of viruses. With such minute things a much greater number is required than in the case of bacteria to obtain that concentration of antigen necessary for the demonstration of precipitation, agglutination, or complement fixation. But given that concentration, these immunological reactions are available for work with viruses, and, as in the case of bacteria, they can be used either in the identification of viruses or in the diagnosis of disease. In connexion with their employment for the latter purpose, however, there is one point to bear in mind: the search for antibody in the blood of the infected individual is likely to be a more fruitful line of investigation than an attempt to demonstrate virus in his tissue by serological means. It is true that Burgess, Craigie, and Tulloch have demonstrated the value of a precipitin test in the diagnosis of small-pox, in which the known factor was a vaccinia antiserum and the unknown a suspension of the crusts from the suspected case, and more recently Craigie and Wishart<sup>7</sup> have

<sup>1</sup> *Ann Inst Pasteur* 1899 13 81<sup>2</sup> *Brit J exp Path* 1935 16 70<sup>3</sup> *Proc roy Soc Med* 1937 31 59<sup>4</sup> *J Immunol* 1936, 30, 169<sup>5</sup> *Med Res Council Spec Rep Ser* 1929, London, No 143<sup>6</sup> *Canad publ Hlth J* 1936, 27, 371<sup>7</sup> *Ann Inst Pasteur* 1898 12 837<sup>8</sup> *Supplement Austral J exp Biol med Sci* 1937 Sept, vol 15

applied the complement fixation test to the same end. But generally speaking the concentration of virus in virulent material from a case of virus disease will fall below the critical level necessary for its demonstration by a serological test *in vitro* whereas with a known virus suspension of adequate concentration the search for antibody in the patient's serum should present no great difficulty

### ZINC SULPHATE SPRAY FOR PREVENTION OF POLIOMYELITIS

Since the publication of a series of disasters following specific vaccination in the control of poliomyelitis the attention of workers in this field has been turned to less heroic methods but whether these are entirely devoid of risk remains to be seen. A further trial of spraying the nose with zinc sulphate solution in an attempt to provide prophylaxis against poliomyelitis has recently been made by a team of Canadian workers.<sup>1</sup> Faced with an outbreak of acute poliomyelitis of considerable magnitude in Toronto in the early weeks of August 1937 they organized, with the co-operation of the public health services a comprehensive scheme which involved the setting up of some eighty nine clinics at different hospitals in the city at which oto-rhinologists attended to carry out the treatment. A brief but intensive propaganda campaign led to an immediate response of volunteers although the number of subjects required for the initial experiment was 5 000 of ages ranging from 3 to 10 years, over 6,000 applications were received in three days the final number being 7 412. Being fully aware of the defects of an earlier experiment of this character the workers so planned the investigation that the test subjects and controls were similar in all respects in so far as it was possible to attain this in human experiments the numbers and ages were approximately the same and the conditions of exposure and risk of attack were comparable. They chose as the prophylactic zinc sulphate as being less toxic and less apt than the alternative substances so far tested to produce permanent ill effects. The first suggestion that the use of chemicals might be effective in the control of poliomyelitis came in 1935 from Armstrong and Harrison<sup>2</sup> who showed by their experiments on monkeys that the application of a 4 per cent solution of sodium alum into the nostrils tended to prevent development of the disease when active virus was afterwards instilled into the nasal passages. Of many chemical substances tested in the same way picric acid and picric alum were found to be the most active. Their findings were

confirmed in the following year by Schultz and Gebhardt<sup>3</sup> who tested forty different preparations on monkeys and came to the conclusion that zinc sulphate being of simple composition and low toxicity was most suitable for trial on human subjects moreover compared with picric alum both rate and duration of protection were rather more favourable.

The first human experiments<sup>4</sup> were carried out in the summer of 1936 in Alabama Tennessee and Mississippi where over two million subjects were sprayed with picric alum solution. The spraying was not done in a uniform manner as regards either technique or the number of applications and the absence of proper controls forbade satisfactory assessment of the results. In the Toronto investigation 1 2 to 1 ccm of 1 per cent zinc sulphate to which was added 1 per cent pontocaine and 0.5 per cent sodium chloride was sprayed by an atomizer into each nostril on two occasions at an interval of approximately twelve days. Much importance was attached to the technique of spraying so as to cover the whole area of mucous membrane and a team of oto-rhinologists carried out the work. Most of the children suffered temporary discomfort such as headache nausea and occasionally vomiting while a few complained of stiffness of the neck or severe transient pain between the eyes. A rise of temperature for a few hours was common. Reactions as a rule were more frequent and more severe in the older children. Despite these unpleasant immediate effects no less than 88 per cent. returned for the second spraying. Loss of smell was observed in just under one-quarter of the number treated. If anosmia is taken as the criterion of complete spraying of the whole area of the nasal mucosa the technique employed must be regarded as faulty. More recently Pentecost has described a method of spraying whereby he claims that anosmia follows in 100 per cent. of cases treated. He anaesthetizes the nasal mucosa with 0.25 per cent pontocaine and 0.25 per cent. ephedrine five minutes before the application of zinc sulphate solution during spraying the patient is in the dorsal recumbent position which is maintained for a full minute to secure even distribution of the solution over the mucous surfaces. The Toronto oto-rhinologists heard of Pentecost's results while the investigation was in process but decided not to change their method which to them appeared satisfactory for the majority of cases.

The final results of the spraying in affording protection against poliomyelitis were subjected to detailed analysis. It is enough to state here that

<sup>1</sup> *Canad. publ. Hlth. J.* 1937 28 523.  
<sup>2</sup> *Publ. Hlth. Rep. Wash.* 1935 50 725.

*Proc. Soc. exp. Biol. N.Y.* 1936 34 13.  
*Publ. Hlth. Rep. Wash.* 1936 51 233.  
*Canad. publ. Hlth. J.* 1937 28 725.

among the 4,713 children sprayed eleven cases of poliomyelitis occurred within thirty days from the second spraying, as one of the eleven occurred between the second and first spraying it is excluded from the analysis, making the attack rate 2.1 per 1 000 cases treated. In the control group of 6 300 children eighteen cases of poliomyelitis (or 2.8 per 1 000) occurred during the same period. The attack rates for the period seven days after the first spraying to thirty days after the second spraying were 1.8 per 1 000 in the test group and 2.9 per 1 000 in the control group. In both sets of figures the differences between the test and control groups were found to be too small to be statistically significant, and the workers were forced to the conclusion that the method of prophylaxis was ineffective in securing the desired end. While nothing has emerged on the credit side, only time can show whether something has to be registered on the debit side. The animal experiments appear to show that the action of these astringent solutions is not a direct virucidal one. It is more probable that a mechanical barrier to the passage of the virus is set up by the formation of a layer of coagulated protein or dead epithelial cells over the olfactory area. Referring to previous experiments with spraying of alum and picric acid we<sup>1</sup> suggested that the possibility of the risk of permanent damage to the nasal mucous membrane had not been fully considered. Whether the trauma to the mucous membrane is transient or may proceed to a chronic inflammatory or atrophic condition is uncertain, as experiments indicate that the protective action only lasts for seven to twelve days. Numerous applications may be found necessary in a prolonged epidemic, and the risk of permanent damage is thereby proportionately greater. Even if the method were proved effective it is unlikely that it would ever be applied in this country so long as poliomyelitis remains a comparatively uncommon disease. For the present one must conclude with regret that a preventive method which held out some hope of success has failed to fulfil its early promise.

### AN UNEXPECTED BUDGET

In pre war days, when Parliamentary debates were waged over expenditures and taxes that now seem by comparison such inadequate causes for so much strife, the issues were at least unclouded by what is nowadays a perplexing complication. The nation's accounts were strictly on a cash basis, and all current expenditure had to be met by current taxation. The war changed all that, as it did so

many other things, and though we struggled to a cash basis, or one that was very nearly a cash basis, the great rearmament scheme which was initiated last year again produced strong and acceptable arguments for meeting a special expenditure in part from borrowings and only the balance by further taxation. This year the general press indulged with some confidence in pre budget speculations that Sir John Simon's well known intellectual gifts and suspected financial skill would enable him to avoid any serious increase in direct taxation, especially in income tax. Some journals besought him to exercise his legal knowledge on the "tax-dodgers," some delivered economic homilies on the ultimate effects of taxation, but all united in suggesting that he would probably be able to avoid increasing the heavy burden of the income tax payer. The Chancellor has gone his own way, and has declined to follow the easier path so generally sign-posted for him, and whether his Budget be regarded as dull and disappointing, or honest and courageous, will depend on the political views of his critics—and perhaps on the extent of the sacrifices the Budget inflicts on them personally. The easy path is often the wrong one, but the other path is not necessarily right because it is hard. It is of course possible that other considerations have entered into the question besides those of national finance. It may be that both at home and abroad good will accrue from so clear a demonstration that the whole country, including the well-to-do no less than the poor, is determined to shirk no sacrifice that may be required to ensure peace and the preservation of the nation's liberty and rightful position in the world. But the price to be paid is a high one. The very small income tax payer escapes scot-free, though the increases in the petrol and tea duties will cost many of them a few shillings a year. Once, however, that class of taxpayer is left behind the additional 6d in the £ imposes a serious burden. To the majority of medical men it will mean practically an additional 10 per cent to the 1937-8 tax. For instance, for that year a married practitioner earning £1,000 a year would, apart from special allowances, be liable to pay £132 10s income tax, the same circumstances in 1938-9 will extract £144 12s 6d. That in itself is an unpleasant enough addition to a year's expenses without taking into account the additions to the cost of petrol used for the work of the practice and of the tea consumed by the household. True the Chancellor promises to give a small increase in the depreciation allowance, but that is a loan rather than a gift, because the more the car owner received by way of depreciation allowances the less he obtains a year or two later when he replaces his car.

<sup>1</sup> *British Medical Journal*, 1937, 1, 1126.  
Ibid. 1936, 2, 1037.

Probably the most general feeling with regard to the Budget is one of disappointment that nearly twenty years after the end of the war that was to end war, our national finances should be so swollen and personal incomes so reduced by the effort however necessary, to avoid another war or at least to be ready to meet one if it should come upon us. That necessity is of course the overriding consideration in which there must be almost universal agreement what is open to argument is the proper ratio between borrowing and taxation as the only sources from which the special expenditure can be met. The decision of the Government is a stern one and the Chancellor of the Exchequer did not exaggerate when he referred to 'the dogged determination and dauntless courage' which it would demand from the nation's taxpayers. Fortunately or unfortunately it is not possible to solve such questions by trial and error. A Government stands or falls by its major Budget decisions and no substantial alteration in the Chancellor's proposal is at all likely. It remains for citizens to shoulder the additional burdens with what grace and fortitude they can muster and hope that so notable a proof of determination will not pass unnoticed by those who have it in their power to help or hinder the cause of international peace.

### THE PLANNING OF MATERNITY HOSPITALS

An interesting paper on this subject by Dr Thomas Orr the medical officer of health for the borough of Ealing was read to the Royal Sanitary Institute on April 21. The paper included an account in some detail of the construction of the Pervale Maternity Hospital which was opened in October 1937. Dr Orr advances sound reasons for dissenting from the recommendation of the Departmental Committee on Maternal Mortality and Morbidity (1932) that new maternity accommodation should when practicable be associated with general hospitals. It is now however generally accepted that this recommendation is not in accordance with the lessons of experience and that whatever may be the case with regard to other special departments of medicine midwifery on a large scale demands a particular specialized environment which can best be provided through an independent organization. The view is generally held in the Public Health Service that in planning a maternity hospital the governing consideration must be the exclusion of known cases of infection and the prompt and effective segregation of all interim cases in which the suspicion arises that infection is developing. It is a regrettable fact that outbreaks of puerperal sepsis of limited extent, still occur from time to time in our maternity hospitals particularly though not exclusively in those whose layout does not comply with the requirements which are now generally accepted. A maternity hospital lacking isolation accommodation in detachment from the main building is an anachronism

—not merely an interesting survival but a positive peril to the lives of the women who are entrusted to its care. The complete isolation of cases of suspected infection which arise within the hospital is a comparatively simple problem the management of cases which are sent to the hospital when openly or potentially infected calls for special arrangements. All large maternity hospitals are not infrequently called upon to receive women in labour who are sent in as 'emergencies' by practitioners who may be unknown to the members of the hospital staff. Such cases must be regarded as potentially infected and therefore as sources of serious danger. These cases should be dealt with in a delivery room which is not used for the general purposes of the hospital and subsequently nursed in an observation ward until it becomes clear either that frank infection is present or that the patient has escaped the risk. Unless the most stringent precautions are taken in dealing with emergency cases the efficiency of the hospital will at times be scaled with results disastrous to the normal cases whose safety is the greatest of all its responsibilities.

### INJECTION RISKS

A fatality in Germany after an injection directs attention once again to the sterilization of syringes. What is the simplest procedure which will obviate all risk? After an injection of luminal into the thigh the patient developed gas gangrene and died; he was suffering from a serious attack of pneumonia. While the risk of death from this alone was material the assumption apparently made by Jungmichel and his colleagues<sup>1</sup> was that gas gangrene began at the site of injection and quickly caused death. The interesting point is that typical *C. welchii* were found in the 70 per cent alcohol in which the syringe was kept. An inquiry at many hospitals showed that in Germany—as probably in this country—syringes and needles are kept in alcohol as a routine in the wards being boiled between successive injections or merely washed with alcohol. As this method has the authority of a number of textbooks and was taught in many universities the medical man was finally exculpated. It is emphasized in the report that Koch as long ago as 1881 showed that anthrax spores resist alcohol and that Wankel in 1926 traced a death from gas gangrene to *C. welchii* spores which were present in the alcohol in which the syringe had been stored. Dalrymple, Champneys<sup>2</sup> and Garrod and Keynes have pointed out the danger of trusting to alcohol for disinfection in certain conditions staphylococci may survive even for several hours and spores have been found in material which had been immersed in spirit for twenty years. C. G. Coulton and G. Sykes in a review of the literature recording infection by spore bearing bacteria stress the failure of ordinary alcohol to kill spores. They found that by adding 1 per cent of various acids or alkali or a cresol derivative the destructive power for spores was

<sup>1</sup> *Monatsschrift für Geburtshilfe und Gynäkologie* 1937 55 1-5  
<sup>2</sup> *Proc. Roy. Soc. Med.* 1937 29 476  
*Brit. Med. J.* 1937 2 123  
*Pharm. J.* 1936 137 73

considerably increased Jungmichel and his colleagues state that the risk of gas-gangrene must be small, for though many deaths from gas-gangrene or tetanus following hypodermic injection are recorded, cases of this kind are very rare in the myriads of injections carried out all over the world. They mention that to every experienced hospital superintendent the occurrence of local sepsis after injection is a well-known phenomenon. They further conclude that since the spores of *Cl. welchii* occur in all garden soil and dust they must be injected very often by patients or by doctors in private practice away from the sterilization resources of a big hospital and that the spores do not germinate unless the condition of the tissue favours this. They therefore warn doctors against repeated injections at the same spot, or injection into the buttock at a place where the muscle is subject to injury in ordinary life. The question then arises, What should replace the condemned practice of storing syringes and needles in alcohol? The ideal is to autoclave every syringe and needle after every injection—an ideal unattainable in practice. The authors suggest that in hospitals syringes and needles should be autoclaved or sterilized by dry heat and each one stored, until used, in a dust-proof package. For the doctor in practice the problem is a difficult one—ordinary boiling in water is not sufficient, and the authors finally recommend boiling for ten or fifteen minutes in water containing 3 per cent soda. Most bacteriologists will agree with the general argument of the German writers, and will advise the prudent practitioner who consults them to boil the syringe and needle for a few minutes in water containing a little sodium bicarbonate, sodium hydroxide or lysol, and thoroughly to wash the syringe through with sterile water before drawing up the solution to be injected.

### RHEUMATIC HEART DISEASE AND THE VAGUS NERVE

For many years the activity of rheumatic carditis in childhood has been judged by the frequency of the pulse as much as by anything else, and a persistently high pulse rate is usually accepted as evidence of marked myocardial damage. A further refinement has been introduced by the electrocardiogram, and a prolongation of the P R interval is now held to be diagnostic of rheumatic heart disease in young subjects provided that syphilis can be ruled out. Dr J. D. Keith in a recent communication<sup>1</sup> has brought forward evidence that over-stimulation of the vagus is the cause of this change and accounts, he suggests, for the prolonged P R interval in mild cases of chorea and arthritis in which there is no clinical evidence of carditis. He found that injection of atropine definitely shortened the P R interval in these cases. Similar experiments were carried out with adrenaline, but the large doses that had to be administered did not decrease the P R interval in rheumatic children to the same extent as did atropine but the decrease was greater than that produced in control children. Another

piece of evidence that Dr Keith brings forward is the fact that abdominal pain and vomiting are not uncommon in children with rheumatic fever, and in the absence of pericarditis, pleurisy, or cardiac failure in such cases he believes the symptoms to be due to over-stimulation of the vagal nerve supply to the gastro-intestinal tract. The origin of the over-stimulation of the vagus appears to be obscure. Certain evidence points to a peripheral abnormality, and it seems more likely that the site of over-stimulation of the vagus is at the nerve-endings rather than at the centre. Dr Keith quotes experiments in which severe heart damage with areas of fibrosis in the muscle followed the administration of acetylcholine to dogs; acetylcholine, it will be remembered, is liberated at the nerve endings of the vagus when it is stimulated. Perhaps in rheumatic fever there is some derangement of the humoral mechanism for transmitting vagal impulses. Dr Keith is continuing his investigations from this point of view, and meanwhile his attractive theories will certainly receive attention from other workers.

### SPONTANEOUS HAEMATOMYELIA

In contrast to vascular lesions of the brain, vascular lesions in the spinal cord are rare. Trauma has long been accepted as the most common cause of haemorrhage into the spinal cord, but recently doubt has been cast on this view by Jefferson, who found that haemorrhage was not a feature of cases in which there was a fatal injury to the spinal cord. It appears likely that in many cases trauma acts only by precipitating a haemorrhage into the cord from vessels in which there is a congenital or acquired weakness of the walls. It is tempting to draw an analogy between such cases and those in which intracranial subarachnoid haemorrhage occurs from rupture of a "berry" aneurysm in the circle of Willis, but aneurysms of the spinal arteries are exceedingly rare. Developmental malformations of these arteries are, however, known to play a part in the production of spontaneous haematomyelia, and in one of Dr J. C. Richardson's four cases,<sup>1</sup> three of which came to necropsy, bleeding from an angiomatous malformation of a spinal artery in the lumbar region was proved to be the cause of the haemorrhage. In another of his cases there was a syphilitic lesion of the spinal vessels, one of which had ruptured. In the third case the source of the haemorrhage could not be determined. As in all vascular lesions of the nervous system the onset of symptoms is sudden, and in spontaneous haematomyelia it is unusual to find any previous history suggestive of vascular disease. This may be explained by the fact that the age incidence, as opposed to that in cerebral vascular lesions, is much lower, the greatest number falling in the third and fourth decades. In the case recorded in the present issue by Dr MacDonald Holmes (p. 946) the patient was a girl of 15 years who, following sudden severe pain in the back and legs, rapidly became paralysed in both legs and developed complete retention of urine. This severe pain, often of a girdle distribution at a segmental

level followed by rapid onset of paresis either of both legs or of arms and legs according to the level of the lesion with complete loss of all forms of sensation below that level is almost diagnostic of haemorrhage into the spinal cord. In Dr Holmes's case it must be assumed that there was haemorrhage also on the surface of the spinal cord because lumbar puncture produced a deeply blood stained cerebrospinal fluid whereas in the cases reported by Dr Richardson in which the haemorrhage was central the cerebrospinal fluid did not contain blood. The prognosis in spontaneous haematomyelia varies according to the level of the haemorrhage as well as with the cause. In Dr Holmes's case in which the sensory level was as high as the second dorsal segment respiratory distress made the outlook appear hopeless but by the use of the Drinker respirator in which the patient was kept for ten days and artificial respiration maintained until the sensory level dropped to the fifth dorsal segment and easy respiration was once more established the expected fatal outcome was averted. Although the paraplegia persisted and sensation returned only slowly the ultimate result was fairly good as eleven months later the patient was able to walk though with difficulty and bladder control was practically unimpaired. Dr Richardson's fourth case that of a man of 38 years also survived his haemorrhage into the cord examination fourteen months after the onset showing only a residual weakness and rigidity of the muscles of the arms and legs. The prognosis in cases in which a fatal outcome does not result immediately from shock or respiratory paralysis or within a few weeks from secondary infection of the urinary tract may therefore be not too bad. It is unlikely however that complete recovery of function will take place owing to gliosis of the haemorrhagic area in the cord this may result in a clinical picture not unlike that of syringomyelia.

### AIRCRAFT REGULATIONS, 1938

On July 1 next the Public Health (Aircraft) Regulations 1938 will come into operation. The document embodying these regulations defines the duties and powers of medical and other officers at aerodromes with regard to aircraft arriving or leaving also the duties of commanders of aircraft. The diseases on which special stress is laid are plague cholera yellow fever typhus and small pox. If for example an aircraft should arrive with a case of plague on board the following procedure must be observed. The aircraft is inspected and passengers and crew medically examined the sick immediately disembarked and isolated all other persons placed under surveillance or in exceptional cases isolated for a period not exceeding six days. Should the aircraft arrive at a sanitary aerodrome further measures are prescribed. Here it should be stated that a sanitary aerodrome is one provided with an organized medical service with a medical officer and at least one assistant with a place for medical inspection with either a laboratory for examination of suspected material or with equipment for taking and dispatching elsewhere such material with facilities for isolation transport and care of the sick for separate isolation of contacts

and for the carrying out of prophylactic measures with apparatus for disinfection disinfecting and deratization with a sufficient supply of wholesome drinking water and with a proper and safe system for the disposal of excreta and refuse and for the removal of waste water. Following the arrival of a plague infected aircraft at such an aerodrome bedding covered linen and other articles are cleansed of vermin and if necessary disinfected merchandise if thought liable to harbour rats or fleas is treated at the discretion of the medical officer such parts of the aircraft as may be considered infected are cleansed of vermin and if necessary disinfected and the medical officer may require the aircraft to be freed from rats. Similar courses of procedure are laid down for observation in the cases of the other diseases named. The issue of these regulations marks a further advance in the provision of health services adapted to conditions of to-day.

### HEALTH IN INDUSTRY

The object of the Industrial Health Education Society has been concisely put by its president Lord Horder in a letter to employers. Our aim is to give the workers information how they can best safeguard their health against the sicknesses and diseases which affect them in the course of their employment and on real matters generally. The annual report for 1937 includes an article reprinted from the periodical *Labour* as an exposition of the Society's work. In this the general secretary Mr James Mackenzie discusses the gigantic wastage caused by sickness and disablement with a loss every year of approximately 28 000 000 weeks to industry. Experience has shown that almost every advance in industrial methods means the birth of some new baffling health problem and that tens perhaps hundreds of workers will suffer and many even die before effective preventive measures can be evolved. In combating the scourge of occupational disease simple rules of hygiene are not always enough specialized information has to be given so that the worker may learn how he can make himself immune to the dangers of his job. Much of this health instruction is provided by the Industrial Health Education Society. During the fourteen years of its existence over 6000 health talks have been given. After each lecture individual health problems arising out of the employment are discussed and the best known methods of combating the particular perils of certain industries are dealt with. The office is at B.M.A. House Tavistock Square W.C.1.

Professor F. R. Frazer will deliver the Croonian Lectures before the Royal College of Physicians of London Pall Mall East S.W. on May 24 25 and 26 at 5 p.m. His subject is "The Clinical Aspects of the Transmission of the Effects of Nervous Impulses by Acetylcholine".

The Earl of Athlone Chancellor of the University of London will open the new Westminster Hospital School of Medicine on Thursday May 12 at 3 p.m.

# SURGICAL PROCEDURES IN GENERAL PRACTICE

*This is one of a series of articles contributed by invitation*

## THE TREATMENT OF OTITIS EXTERNA

BY

F C W. CAPPS, F R C S

### Classification

The affections of the auricle and surrounding skin, external meatus, and outer surface of the drumhead which are included in the term "otitis externa" may be grouped (1) according to the infecting agent, (2) according to clinical type. Under the former heading the staphylococci, *albus* and especially *aureus* are common offenders, aided in the seborrhoeic subject by the acne bacillus and pityrosporon. The haemolytic streptococcus comes a good second. In the former the pilo-sebaceous follicles are usually attacked, and may give rise to a boil, in the latter the deeper layers of the epidermis are infected, resulting in vesicles, fissures, ulceration, diffuse cellulitis, or erysipelas. Infections that occur more rarely are due to various moulds (otomycosis), the Klebs-Loeffler bacillus (croupous otitis externa), the tubercle bacillus, and other organisms. Clinically we have

#### (1) Chronic conditions

Chronic seborrhoeic or "eczematous" dermatitis  
Otomycosis

#### (2) Subacute conditions or chronic conditions liable to exacerbations

Acute seborrhoeic dermatitis  
Acute (impetiginous) dermatitis  
Recurrent furunculosis

#### (3) Acute conditions

Acute diffuse otitis externa (usually a meatitis)  
Acute circumscribed otitis externa & furuncle  
Erysipelas  
Acute haemorrhagic otitis externa  
Perichondritis

### Contributory Causes

These may be constitutional—debilitated or depressed states (test the urine), or local—the seborrhoeic scalp, the irritating and infecting discharge from an otitis media, impacted wax. Finally, trauma may play a part; either self-inflicted by scratching or the use of matchsticks etc., or due to careless or septic instrumentation.

Although I have put the contributory causes last, they are very important where treatment is concerned. Patients must be warned against scratching and poking their ears, and in the case of babies and young children this may be prevented by splinting the elbows. It goes without saying also that any practitioner who examines an ear or uses instruments therein should do so only under direct vision and with aseptic precautions. Local measures alone will not clear up a succession of boils in a poorly nourished or overworked body needing a holiday, and to treat an intertrigo or eczematous meatitis, which are a local spread, and leave the seborrhoeic scalp untreated is a waste of time.

### Examination

Before any treatment is undertaken a careful examination must be made of the affected parts, and if possible the drumhead should be inspected. For this

purpose a few instruments are essential. An electrical self-illuminating auriscope is a very nice piece of apparatus for the inspection of a drumhead at the bottom of an unobstructed passage, but it is not easy to dry a meatus, remove debris, or insert therapeutic applications through it, and for these manoeuvres (which must be done under direct vision) a head mirror, or head lamp and a set of different-sized specula are much better. I prefer the type of speculum shown in the illustration, and usually

known as Keen's pattern, but everyone will have his particular liking in this respect, the only specification being lightness, moderate size, smooth rounding of the narrow or meatal end, and an easy grip for finger and thumb at the larger end. Add to these an aural syringe, a pair of light angled forceps (Keen's pattern, as illustrated, is satis-

factory), one or two fine wool-carriers, and possibly a fine, light, and not sharp right-angled hook for loosening and pulling out debris. Stainless steel, when available, is an economy in the long run. The syringe should be of all-metal type, and should take to pieces for cleaning and greasing. The nozzle should be fine, tapering, and smooth-ended not bulbous, a "bayonet" fitting allows of its easy and rapid removal for filling the syringe. As the syringe must be controlled by one hand there must be finger rings at the proximal end, and it is wise to choose a syringe of a size that will suit your "span" when full. A word of warning here—always see that the component parts are firmly fitted together before use, and tip the nozzle up and empty the syringe of air. Nothing is more horrible, and to a child even frightening, than a blast of bubbles in the meatus.

When syringing, gently hold the pinna out and slightly upwards with the finger and thumb of the disengaged hand. Carefully cleanse out the auricle first and then approach the meatus cautiously especially in children. Insert the nozzle and direct the stream upwards and backwards unless there is an obvious boil or tender swelling in that situation. In this direction a fair amount of force can safely be applied without causing pain at the drumhead, and most debris will be washed out by the return flow. For drying, the best quality fine white wool is advisable. Handiest of all are the small cardboard packets of sterilized wool used by dentists from which as much as is needed can be pulled through a small hole. The wool may be used with forceps as thin pludgets or firm

rolled in a thin flat piece on to an applicator so as to leave the end soft and fluffy. Sometimes when the deeper parts of the meatus or drumhead are difficult to see the swelling of the walls may be reduced by the insertion of pledgets soaked in cocaine 5 per cent and adrenaline 1 in 1 000 in equal parts.

### Differential Diagnosis

So important is the distinction between an otitis externa and an otitis media with mastoiditis that no apology is made for including here three cardinal points of difference. It should be pointed out that in very painful cases it may even be necessary to give an anaesthetic for diagnostic examination.

#### *Post-auricular Oedema due to Furuncul or other Acute Inflammation of External Parts*

1 Drum membrane usually intact and may be normal or only slightly congested

2 Pressure upon tragus and manipulation of auricle causing movement of fibro-cartilaginous meatus usually result in severe pain

3 Pressure over the mastoid process just behind the post-auricular sulcus and opposite the orifice of the meatus will if so directed as not to disturb the position of the auricle cause absolutely no pain. The oedematous tissues pit deeply under the compressing finger after which no bone tenderness can be elicited. Pressure at exactly the same point but directed slightly forwards so as to disturb the auricle causes severe pain.

#### *Post-auricular Swelling due to Acute Suppurative Mastoiditis*

1 Drum membrane usually perforated and always shows some of the cardinal signs of suppurative otitis media

2 Pressure upon tragus and manipulation or movement of fibro-cartilaginous canal cause absolutely no pain

3 Firm pressure upon the mastoid process just behind the post-auricular sulcus and opposite the orifice of the meatus usually elicits deep-seated bone tenderness.

### Treatment

This is largely a question of cleansing, drying the application of suitable salves, the treatment of pain and the prevention of reinfection. Now and again but very rarely, the knife is needed and in certain cases specific treatment is indicated. So far as general treatment goes it is probably wise to make it a rule to treat all bad cases of boils or otitis externa whether febrile or not in bed preferably in an institution where all facilities are available. Owing to the tightness of the integument the pain of a bad boil in this region can be maddening—far worse even than a mastoiditis—and the debilitation of the patient is in proportion. The diet should be light and plain and alcohol should be avoided in the acute stage as the throbbing set up by even a small quantity may be intense. On general principles an initial purge is advisable. Plenty of fresh fruit and fruit drinks may be given.

In the treatment of pain there is very little to touch aspirin for inducing sleep aspirin should be followed some fifteen minutes later by a hypnotic. Local and specific treatment will be discussed under each type separately.

For cleansing plain boiled warm water a solution of bicarbonate of soda—a drachm to the pint (especially where waxy debris has to be cleared)—boric lotion or dettol 1 in 20 are all suitable. Dry scabs and scaldiness may be removed with the aid of spirit soap. Peroxide either as drops or lotion should never be used. There is no particular virtue in it and the irithness merely makes the epidermis sodden and tends to spread the

infection. No patient with active or potential otitis externa should allow water to get into the ears except—and that not more frequently than is absolutely necessary—for cleansing purposes after which they should be thoroughly dried and may even be desiccated by swabs dipped in 95 per cent alcohol.

### Chronic Seborrhoeic Dermatitis

This is common in adults and takes either the form of dry scaldiness which when shed leaves a glazed sensitive surface or of thickening and desquamation with infection and fissuring and blocking of the meatus with debris.

The scalp should first be treated with frequent spirit soap shampoos followed by thorough rinsing and this should be continued at regular intervals after the ears have returned to normal. At the same time the meatuses should be thoroughly cleansed of debris if possible without syringing but better with it if attempts at dry removal are likely to lead to trauma. The skin of the meatus and any affected area on the pinna should then be smeared with a thin film of ung. hydrarg. oxid. flav. or zinc oxid. cream. The first cleansing should be done and the first one or two applications made by the practitioner himself. He can then train the patient to smear in the ointment on a wool-headed matchstick. To make this strike the match and then blow it out. A piece of fine wool is then firmly rolled around the blackened end between the finger and thumb so as to leave plenty of wool over the end. The patient should learn to introduce the applicator with a gentle rotatory movement. When well an occasional smear in both meatuses should be a lifelong routine along with the treatment of the scalp.

### Otomycosis

This is not very common in temperate or cold climates as the growth of the fungus often an *aspergillus* is favoured by warmth and moisture. The mouldy appearance in the meatus is unmistakable. Otomycosis is relatively harmless and painless unless the mycelia invade deeply to the bone or through the outer layers of the tympanic membrane. It may set up an inflammation which leads to secondary infection. The essential treatment is to avoid water and all oily or fatty applications. Even glycerin favours its growth. Spirit is the only application necessary. As much of the fungus as possible should be carefully swabbed away and the patient given 95 per cent alcohol drops to instil twice daily.

### Acute Seborrhoeic Dermatitis

This is merely a further stage of the chronic condition with much soreness and fissuring which may lead to secondary infection and boils or cellulitis. All fissures of the meatus, pinna and post-aural sulcus should be cleaned and painted with a strong solution of silver nitrate or cauterized with a silver nitrate pencil. Otherwise the treatment is mainly as above. Unguentum calamine or the lotion is useful for the pinna and surrounding skin. If there is much excitation in the meatus an ointment containing 10 grains of salicylic acid to the ounce may be used and in very severe cases one or two skin doses of tr. rays may be tried.

### Acute (Impetiginous) Dermatitis

This is most often seen in children and may be associated with an otorrhoea or dry scalp. Small pus-filled form which burst and become covered with yellow crusts.

There is often an associated lymphadenitis. It should be treated as an impetigo, and risk of contagion avoided. The hair should be cut well back from the ear or combed up and held back by a band. The crusts should be bathed away frequently and the raw surfaces covered with a smear of one of the zinc ointments mentioned above or ung. hydrarg. ammon. dil. It is a good plan to cover with a protective dressing at night to prevent scratching and the infection of other areas via the pillow. Any cause of reinfection such as pediculosis or otitis media must be treated. If there is much discharge from the meatus a wool swab may be loosely inserted, but all parts with which it comes in contact should be well greased to prevent it sticking and pulling away the inflamed epidermis.

### Furunculosis

Boils in the ear may be single or multiple, and often a single boil will just have cleared up, only to be followed by another owing to the infection of a neighbouring hair or sebaceous follicle by the discharge from the first. The prevention of reinfection is therefore of prime importance. This may be accomplished (1) by protecting the rest of the meatus, (2) by specific anti-staphylococcal treatment. The meatus should be cleansed, dried, and mopped out with 95 per cent spirit. In all stages—irritation, swelling, and necrosis—I have found that the best treatment thereafter is to pack the meatus fairly tightly with a wick of half-inch ribbon gauze thickly impregnated with a paste composed of exsiccated magnesium sulphate, 2 parts, and glycerin with  $2\frac{1}{2}$  per cent carbolic acid, 1 part, by weight. This should be changed once or twice in the twenty-four hours, the meatus being carefully cleansed each time, and the process continued as long as there is any swelling or a discharging fistula. The paste, being very hygroscopic, reduces the oedema and congestion, and the wick, by separating the opposing walls of the meatus, prevents cross-infection. If this treatment is continued for long the skin at the entrance to the meatus and over the lobe may become sore and cracked. This is best avoided by smearing with zinc ointment before inserting the wick.

Heat is comforting, and may be applied whether a wick has been inserted or not, either as poultices, a rubber hot-water bottle, an electric eye-pad, or as short-wave diathermy if available. The extravagant claims made for the last-named hardly appear to be substantiated by personal experience, but the comfort of the application is undoubted. As soon as the boil has aborted or has run its course, the core is expelled, and the fistula scabbed over, the meatus should be cleansed with spirit and smeared with a protective coating of ung. hydrarg. oxid. flav., which should be repeated nightly for some days.

The ordinary boil is much better not incised, but now and again a boil will burrow deeply and give rise to a meatal abscess, and then incision may be necessary. If there is no doubt as to the diagnosis, cutting is best done with a small curved bistoury or a furuncle knife through the meatus. Occasionally there may be a doubt as to whether a fluctuating post-auricular swelling is a meatal abscess, suppurating glands, or a subperiosteal abscess from a mastoid. Then it may be necessary to open for diagnostic purposes behind the auricle to see whether the collection is merely in the superficial tissues or whether bone has been bared.

In all staphylococcal infections specific treatment should be tried at the same time as local measures. Collosol

manganese intramuscularly or by mouth, stannous oxide by mouth, yeast, etc., are all successful in some cases, none in all. In recurrent cases vaccines, either stock or autogenous, should certainly be tried, but in my experience they are of no use unless the dose is carried much higher than usually recommended—up to 2,000 or 3,000 millions of the ordinary vaccine, for example.

### Acute Diffuse Otitis Externa

This may be staphylococcal, but it is more commonly streptococcal. It is characterized by uniform swelling of all the walls and great narrowing of the meatus. It may not be possible to insert a wick, but glycerin and carbolic (2 per cent) drops can usually be instilled, and heat should be applied. If a haemolytic streptococcus is the causative organism, prontosil or its derivatives should be given.

### Erysipelas

This has the characteristic raised edge at the margin of the inflamed area, but may be missed unless the patient is examined in a good light, preferably daylight. The danger is that the exquisite tenderness may lead to its being mistaken for an acute mastoiditis. Until quite recently it was a safe bet that if you had the infection over one ear it was certain to reach the other, and it might travel the circumference of the head anything up to three times before dying out, no treatment, local or general, being of avail. Prontosil has definitely changed all this. Probably the best local application is calamine lotion. The infection very often starts from a fissure, this should always be looked for, and should be dealt with after the acute infection has subsided.

### Acute Haemorrhagic Otitis Externa

This fortunately is rare, but it is sometimes seen in epidemics of influenza. The walls of the meatus and outer surface of the drumhead are covered with haemorrhagic blebs, and the differentiation from acute otitis media may be difficult. Cocaine and adrenaline pledgets will often help to determine the outlines of the drum, and mobility of the latter on self-inflation is against middle-ear infection. Treatment is by glycerin and carbolic drops, dry heat, and prontosil.

### Perichondritis

This usually arises as a result of exposure and infection of the cartilage of the pinna or meatus by operation or injury. It is a serious complication, as the cartilage offers no resistance and the resulting deformity may be severe. Abscesses must be opened and drained, but precipitate surgery is best avoided. It is unwise to incise the cartilage owing to the risk of this complication. A "cauliflower ear" is usually a better sight than the results of perichondritis.

S. Miglioli (*Ann. Ist. Carlo Forlanini*, November, 1937, p. 60) states that injection of alcohol into the intercostal nerves in thoracic herpes zoster was suggested by E. Morelli in 1926, but was not carried out until 1936 by Buttafari and Cerulli. Miglioli reports the case of a girl, aged 17, under treatment for pulmonary tuberculosis by bilateral artificial pneumothorax, who developed herpes zoster over the area corresponding to the sixth to the eighth ribs on the left side accompanied by considerable pain. After injection of alcohol into the intercostal nerves for four days the pain completely disappeared.

## VULVO-VAGINITIS IN CHILDREN

### CLINICAL AND ADMINISTRATIVE ASPECTS

The following abridged account of vulvo-vaginitis in children is extracted from a report drawn up by a Departmental Committee appointed by Sir Frederick Menzies Medical Officer of Health to the County of London to investigate the clinical aspects of the morbid conditions included under the designation vulvo-vaginitis and to consider the means necessary to prevent the spread of the disease in hospitals' nurseries and schools in which children may be resident. The full text of the article has been issued for publication under the authority of the Hospitals and Medical Services Committee of the London County Council. The members of the Departmental Committee who are its joint authors are

The term vulvo-vaginitis includes a variety of conditions varying greatly in their clinical manifestation in the causal organism in infectivity and in the readiness with which they yield to treatment. Characteristically a vaginal discharge is found and may be profuse but frequently only a soreness and irritation of the vulva are present. The vulva and introitus are found to be reddened and possibly oedematous. There may be enlargement of the inguinal glands. Frequency of micturition is of common occurrence. Abdominal pain is not common.

The condition may develop as a complication of a general infection (for example chicken pox or pneumonia) and there may be septic foci elsewhere in the body. A history of masturbation is not uncommon.

### CLASSIFICATION

The best classification of vulvo-vaginitis for practical purposes is considered to be (A) gonococcal and (B) non gonococcal. It is true that some serious cases of infection by the streptococcus or other organisms may be as intractable and as difficult to treat as those due to the gonococcus but gonococcal vulvo-vaginitis stands out as a recognized clinical entity and presents peculiar problems of its own.

The London County Council has had a wide opportunity for gauging the relative frequency of the two varieties of vulvo-vaginitis as it has for over two years maintained a very careful watch for the occurrence of this disease among the many thousands of children sick and healthy under its care. The results for that period may be summarized as follows.

Hospital or School	Cases of Vulvo-vaginitis	Gonococcal Cases
20 general hospitals	523	13
20 special hospitals (including children's, tuberculosis, and fevers)	24	13
20 residential schools and homes	50	—
15 nurseries for healthy infants	17	—
	614	32

At the Hospital for Sick Children Dr. Nabarro divided a series of 1,219 cases into 249 gonococcal, 949 definitely non gonococcal and 21 doubtful. From our patients only the following figures were obtained.

	Total	Positives	Negatives
1930	134	14	120
1931	123	12	111
1932	113	19	94
1933	125	10	115
1934	131	11	120
1935	116	17	99
1936	153	24	129
	955	117	838

It is obvious that these series were to a certain extent selected. The Council's proportion of positives was too low because known gonococcal cases would be diverted at once to St. Margaret's Hospital and would never enter a general hospital. The Great Ormond Street figures are too high as the hospital has a V.D. clinic to which known cases are naturally sent. This is proved by an analysis of the gonococcal cases for 1937. Out of 16 positive cases 9 came from other hospitals, 3 from child welfare centres, 4 from casualty department or outpatients. The fact emerges however that vulvo-vaginitis is only in a small minority of cases gonococcal, a point which is perhaps not widely appreciated.

The classification between gonococcal and non gonococcal is necessary for administrative and clinical purposes and in order to form a clear picture of the disease vulvo-vaginitis but it may be pointed out that no useful purpose is served by emphasizing it to the lay public especially to parents. Vulvo-vaginitis in children is only very rarely a venereal disease. The gonorrhoeal infections of children are in the vast majority of cases non sexual in origin and it is really an accident whether the causal organism of vulvo-vaginitis is a gonococcus, a streptococcus, a *B. coli* or any other.

### NON-GONOCOCCAL VULVO-VAGINITIS

This disease causes the gravest anxiety to all responsible for the health of children owing to its great infectivity, resistance to treatment and the horror it excites in the public mind. Its incidence is very difficult to gauge as it is of course not notifiable and there is a very motive against publicity when outbreaks occur. The number of cases of non gonococcal vulvo-vaginitis in children under the age of 14 coming under hospital or clinic treatment in London in 1936 may be estimated as follows.

St. Margaret's Hospital	22
Hospital for Sick Children, Great Ormond Street	24
London Lock Hospital	14
Children's Medical Home, Waddon	—
V.D. Clinic, Lambeth Hospital	34
	100

This list inevitably excludes cases treated in private but it does include an unknown number from the Home Counties.

### Mode of Infection

Infection with the gonococcus in female children is usually accidental and is a result of contamination of the vulva with such infected fomites as towel sponge, bed linen, or lavatory seat. The high incidence of infection in the parents of these children points strongly to this mode of transmission especially in poorer homes where accommodation is inadequate. This fact emphasizes the need to make every effort, through venereal clinics and other suitable channels, to impress adult sufferers from gonorrhoea with the necessity for protecting from infection any children with whom they come in contact. The contacts of known cases of gonorrhoeal vulvo-vaginitis (for example parents and sisters) should always be examined to exclude infection.

Direct infection by assault does occur, but it is not a common cause in this country. In institutions the infection may be spread by bed-pans, bed-pan covers, lavatory seats, towels, flannels or sponges, nurses' aprons, clinical thermometers (if rectal temperatures are taken), or enema nozzles, hence rigid precautions must be taken.

The vulva of a child is relatively unprotected until the labia majora develop and so is more exposed to these indirect modes of infection than in the adult. The mucous membrane too is thin and less resistant to infection. After the first few weeks of life the vaginal secretion is scanty and alkaline. With the approach of puberty the secretion increases and becomes strongly acid and bactericidal, and Doderlein's bacillus is found in large numbers in normal smears. This acid reaction probably explains the lower incidence of infection in young babies and girls over 10 years of age.

The inflammation and oedema of the urethral meatus and hymen are very typical of gonococcal infection. After careful swabbing of the vulva a probe passed into the urethra shows pus in the majority of cases. The pus spreading back over the perineum may cause a rectal infection. The anus is red and moist. There is sometimes mucus on the faeces. The first rectal test may be negative, but if the vaginal discharge does not clear the tests should be repeated at intervals otherwise an infection may be missed and then re-infection from the rectum may occur later.

The exact limits of the incubation period are difficult to determine. In the great majority of cases it is three to four days, but may in rare instances be longer.

### Symptoms and Clinical Signs

There may be a complaint of vaginal discharge with burning or irritation of the vulva in young children, discomfort on walking or frequency of and pain on micturition. The lack of symptoms is often surprising, particularly in older children, and the mother brings the child to the doctor because the discharge is found on the clothing.

In a chronic case there is a slight inflammation of the vulva and vagina with usually a scanty discharge which may be thin purulent or muco-purulent. The mucous membrane of the vulva is injected, particularly in the deep clefts between hymen and labia minora and just within the urethral meatus. The hymen is frequently torn and stretched. The cervix should be examined in these cases.

In an acute case the diagnosis can readily be made on clinical signs alone. The vulva is hyperemic or acutely inflamed and bathed in pus which oozes from the vagina with an expulsive effort on the part of the child. The pus may be thick or thin, yellow or greenish. It is rarely blood-stained and never so offensive as in the case with foreign bodies in the vagina. In neglected cases there is excoriation of the labia majora, groins, and inner surfaces of thighs, with adherent crusts of dried pus.

The closest co-operation between the clinician and the bacteriologist is necessary especially in doubtful cases. At the same time too exclusive dependence on bacteriological findings is to be deprecated. In acute cases the clinical appearances of gonorrhoea should leave little doubt as to the diagnosis.

### Collection of Material for Bacteriological Diagnosis

The manner in which material for bacteriological examination is collected is of great importance. Many failures to make a correct diagnosis are due to the fact that bacteriologists are supplied with material taken by unsuitable methods or by unskilled workers. Swabs should be taken only by a clinician expert at the task and never delegated to a member of the nursing staff unless she has been specially instructed. No attempt should be made to work single handed. At least one assistant is essential to hold the child still in the correct position.

The child is placed in the dorsal position with the knees drawn up and the thighs separated as far as possible without hurting the child, the external genitalia being exposed in a good light. Any superficial discharge is removed with wool and the labia separated with gloved thumb and forefinger of the left hand.

Two swabs are taken with wooden or wire applicators round which a thin layer of good quality sterilized cotton wool is firmly wrapped. The probe must be passed well into the vagina and withdrawn with some discharge on it. The first swab is used to make a thin even smear on a clean glass slide, the film is allowed to dry in air and is then preferably fixed by being passed through a gas or spirit flame several times after which it is wrapped in paper and placed in the special slide box supplied for the purpose. Smears should never be packed while still moist. The other swab is used for inoculation of the culture medium, which may be done at the bedside or the swab may be transported as quickly as possible to the nearest laboratory.

Smears and swabs for culture should be taken from these sites in proved gonococcal cases or in patients suspected of past or present gonococcal infection or where there is any other special indication. Swabs may be taken from the urethra in a manner similar to vaginal swabs. The child should not have passed urine within an hour, and preferably longer, of being examined. Swabs of rectal mucus or muco-pus should be examined where there is clinical evidence or suspicion of rectal infection.

### Identification of Infecting Micro-organism

It is generally agreed that for primary diagnosis both smears and cultures should be examined wherever possible. This is particularly essential in the case of suspected gonococcal infections, since (a) Gram negative diplococci other than the gonococcus are occasionally present in the vagina and (b) a diagnosis of gonococcal infection on smear alone will not be accepted in any medico-legal proceedings. However, on finding typical Gram negative diplococci in the smear of a purulent vaginal discharge a preliminary report should be sent (or telephoned) in some such form as this: 'Gram negative intracellular and/or extracellular diplococci morphologically resembling gonococci are present in smear'. It is helpful if on receipt of this preliminary report, the clinician sends a repeat smear and swab for examination at the laboratory. A further report is sent on the result of the cultural examinations.

Most workers seem agreed that the complement fixation test is usually negative in the early stages of a gonococcal infection and that therefore it plays little part in the early diagnosis of vulvo-vaginitis in children. The evidence as to its value in the later stages of infection is still rather conflicting. It is certain however that the test should not be regarded as an alternative to careful examination of films and cultures from the mucous membranes especially in the early stages of an inflammation. Definite cases of gonococcal vulvo-vaginitis may have a negative complement fixation test throughout the attack.

### Complications

Cervicitis is one of the common causes of recurrence, and it is possible that it is present in the majority of cases in the early stages. The cervix should not be examined as a routine but only in those cases which fail to clear up with the usual methods of treatment or which relapse after treatment ceases.

Ascending infection through the internal os causing an endometritis salpingitis or pelvic peritonitis occurs rarely. Although urethritis is so usual, cystitis is a very rare complication. Cases of gonococcal conjunctivitis and iritis are very uncommon. They have never occurred as a complication in the series of cases at the Children's Medical Home, Waddon. There have been four cases of purulent conjunctivitis but gonococci have not been found.

When dealing with infants it should be remembered that vulvo-vaginitis may occur concurrently with gonococcal ophthalmia but not as a rule during the first few weeks of life since at this period the vaginal epithelium is of the adult type and the secretion highly acid—conditions inimical to infection with the gonococcus. Later a vaginitis in a child with ophthalmia may be overlooked as the eye condition is more serious and attention is focused on this. Ophthalmia as a secondary complication of gonococcal vulvo-vaginitis is a very rare occurrence.

### General Treatment

**General Nursing Instructions.**—The careful nursing of all children collected in hospitals and in institutions is of the highest importance in the prevention of vulvo-vaginitis. As regards the nursing of children affected with any form of vulvo-vaginitis the following measures are recommended: (a) Certified nurses only shall be employed in the care of affected children until three negative swabs have been obtained in a period of not less than a week and the condition is considered to be non-gonococcal on clinical grounds. Nurses employed in the care of affected children must not while so employed attend to unaffected children but they may with suitable precautions attend to adult patients.\* (b) Every affected child should have a separate bed pan or chamber unless provision is available for efficient sterilization of such utensils after use. (c) Special attention should be paid to the clothing of infected children. When the discharge is profuse a light pad or non-irritating material is advisable so as to minimize friction. All infected clothing should be soaked in a suitable disinfectant before being sent to the laundry.

**General Routine.**—This should include all procedures likely to help in "building up" the resistance of the patient and may in certain cases be the most important factor in arresting the infection. (a) In patient treatment with rest in bed during the acute stage for one to three weeks (according to the severity of the case) is to be recommended and is essential to relieve the initial soreness of the vulva. (b) Balconies or gardens are recommended in which infants can lie and older children play for most of the day after the initial period of resting in bed. It should be realized that excessive exercise may have a detrimental effect. (c) The provision (when possible) of some occupation for the children such as organized games, singing and elementary lessons all help to prevent the dangers of "idle hands." A nursery governess is of the greatest assistance as she removes the children temporarily from the care of the nurse in uniform and the association of hospital in the child's mind. (d) A balanced diet is to be desired: milk, fruit and fresh vegetables are necessary and an excess of carbohydrate is to be avoided. (e) Ultra violet light for use during the winter and for specially debilitated children may be a useful adjunct. (f) Nurses responsible for the care of gonococcal vulvo-vaginitis cases should be specially trained.

### Local Treatment

The following choice of methods is suggested. It is emphasized that no packing of the vagina should be carried out and that throughout only non-irritating solutions should be employed. The vulva should be swabbed with lotion and dusted with a drying powder as often as necessary to keep it free from pus and as dry as possible. If the discharge is profuse a sitz bath may be given as a preliminary to treatment to make the cleansing of the vulva easier.

**Douching** may be necessary to remove excessive vaginal discharge and may be employed as a routine method of local

\* In hospitals for infectious diseases, barrier nursing of the case may be substituted at the discretion of the medical superintendent for removal from a children's ward.

treatment. The following solutions may be used: protargol 1 g per cent. tinct. iodine 1 drachm to 1 pint dist. of 1-2 drachm to 1 pint solution of chloramine T 1-2 per cent. (The two latter are useful in offensive cases.) A rubber catheter may be attached to a douche can or to a Higginson's syringe. Solutions (as above) may be used conveniently at 80 to 100 F. It is suggested that a rotation of the solutions used is advisable every two weeks.

**Swabbing.**—Opinion differs as to the value of swabbing or painting the vagina. Some authorities recommend it as a routine treatment to be applied except when it causes pain or the child is very nervous. Others restrict its use to cases where other treatment has proved ineffective and to very small infants while one authority considers other forms of treatment adequate and does not employ it at all. It carried out one of the following solutions should be used applied to the vagina on dressed throat swabs or wooden applicator: 10 per cent. protargol in glycerin, 10 per cent. miltol in glycerin, 5 per cent. mercurochrome in glycerin. Dressed Plastair probes may be used for the purpose in older children.

**Urethral Treatment.**—Here again practice differs. Routine swabbing or painting with 5 per cent. protargol or 1 to 2 per cent. silver nitrate is recommended by some when the canal is involved unless contraindicated as above. Other authorities depend upon alternative forms of treatment.

**Rectal Treatment.**—Swabbing is used at all, should be restricted to cases in which the rectum has been found to be infected with the gonococcus and carried out with the greatest care but some authorities are not in favour of this form of local treatment of the rectum.

It is emphasized that probes should be careful and evenly dressed and with the best quality cotton wool.

### Special Treatment

**Vaccine Therapy.**—A reliable stock gonococcal vaccine may be used but the use of this form of therapy appears to be infrequent and some authorities are definitely opposed to it. It has been recommended in chronic cases where there have been relapses and in the rare cases of tenosynovitis or arthritis. It should never be given during the acute stage.

**Oestrin.**—Many observers have reported favourable results on the use of oestrin. It can be given by mouth by injection or in the form of suppositories, the dosage being approximately five times as great by mouth as by injection. The oestrin used is probably to be preferred as children do not object to it and the daily insertion of a vaginal suppository is considered undesirable and a procedure to be avoided if possible. The daily dose is 5000 to 6000 units according to the size of the child and it may be given at one time or every morning. The character of the discharge macroscopic and microscopic should be noted every day. The purulent gonococcal discharge soon gives place to one containing many squamous epithelial cells and Doderlein's bacillus but no gonococci. The duration of the treatment varies from a few weeks to a few months. If the urethra or rectum (which are not affected by the oestrin) is found to be infected treatment should be applied in the manner indicated above. Relapses may occur after or even during a course of oestrin and are then usually found to be due to a urethral or rectal infection. These usually clear up quickly with oestrin and the local treatment of the urethra or rectum. It is important that the change in the character of the discharge mentioned above is brought about. Unpleasant effects such as enlargement of the breasts, vaginal haemorrhage and especially muscular pain have been ascribed to the use of oestrin by some observers. The great value of the drug is however firmly established in the view of many experienced clinicians.

**Sulpharilamide** and allied substances have been used in some cases with encouraging results but it is too early at this stage to assess fully the value of this treatment. Attention is drawn to the varying degree of efficiency in the preparations of both oestrin and sulpharilamide now on the market. If good results are to be obtained the selection of a reliable preparation is essential.

### Relapses

The tendency to bacteriological and clinical relapse is one of the features of this disease. It is important to recognize the fact that these relapses may sometimes be of very short duration and pus may be present only for a few hours. A test may be positive on one day and when repeated the following day for confirmation a negative result may be obtained. There may be no clinical signs in these latent cases, but the gonococci may be found in apparently clear mucus.

Relapses may be due to reinfection from an insufficiently treated urethra or from the cervix or rectum, but masturbation is a contributory factor. It is the persistence of this habit after treatment has ceased which makes a clinical diagnosis of cure very difficult in many cases. Reliance on the bacteriological reports is essential. The influence of bad hygienic conditions at home of tight and dirty clothing and of masturbation in prolonging an unhealthy appearance of the genital parts should not be forgotten. From 11 or even 10 years onwards the physiological changes of puberty may be responsible for intermittent congestion of the parts, moisture and mild leucorrhoea. None of these conditions should be mistaken for a genuine relapse. It is impossible to arrive at a correct diagnosis in such cases without the help of an experienced bacteriologist. Films and cultures (the latter being the more important in chronic or latent cases) must be taken.

It is of importance to remember the importance of *cross-infection and reinfection* when considering apparent relapses. Very great care is required to prevent convalescent cases of vulvo vaginitis in a hospital being reinfected by children still in the acute stage. It may also happen that a child discharged from hospital may be reinfected in her own home (perhaps by the original source of infection), and then brought back to hospital with a complaint that she has relapsed.

The intractable character of gonorrhoeal vulvo vaginitis is shown by the long period of treatment and observation required—for example up to two years even when the case is in skilled hands from the beginning.

### Criteria of Cure

Of all the vexed questions associated with vulvo vaginitis none has given rise to greater controversy than 'When is the child cured?' The marked tendency to bacteriological and clinical relapse, the uncertainty of finding the gonococcus in chronic discharges and the obvious difficulty of proving a negative lead to the necessity for extreme caution in giving a certificate of cure. The query cannot however, be evaded. Anxious parents must be reassured schools must be advised when they can safely readmit pupils, and hospitals want to know when they may finally discharge patients.

The problem is peculiarly difficult of solution because the clinician is not only required to determine whether a child patient is at any particular moment free from infection but also when the liability to relapse has ceased. As against an excessively pessimistic attitude it is pointed out (1) that there is no direct evidence of gonococcal infection contracted in childhood lasting into adult life. Large numbers of patients who have suffered from gonococcal vulvo-vaginitis have now been followed up for many years and no such case is known. Moreover the previous history of thousands of adult patients who have attended the V.D. clinics during the past twenty years has been recorded with care and no such tendency has been noted. (2) Exacerbations commonly occur in the early stages after treatment has ceased although rarely after three months.

*Criteria of cure should be negative tests (films cultures and gonococcal complement fixation) for a minimum of four months after cessation of all treatment. During this time the patient should be under observation at frequent intervals.*

Daily inspection of the vulva is advisable for the first three months after suspension of treatment in view of the very short duration of some relapses. (This can be done quite adequately by an intelligent mother after the first few weeks.) Normally the vulva clears up completely after treatment, but in a few cases there may sometimes be a persistent redness and slight discharge which is not pathological.

After treatment has been discontinued a full set of films and cultures should be made from vagina, urethra, and rectum (if considered advisable). For a minimum of four months vaginal and urethral swabs should be taken at weekly intervals for the first three weeks, and subsequently at intervals of two or three weeks. Tests from the rectum need not be repeated as a routine unless it has been infected. The final set of swabs and cultures should be taken after a provocative dose of vaccine administered twenty four hours previously.

The place of the complement fixation test among the criteria for cure of gonococcal vulvo vaginitis is still undecided. When performed in a laboratory where such tests are being done weekly on a considerable scale and under well controlled conditions—the L.C.C. laboratories come into this category—the test has been helpful. When both the bacteriological and serological tests are negative cure may be assumed. When the bacteriological test is negative but the complement fixation test remains positive for more than six weeks persistence of some hidden focus of infection may be suspected. Such persistently positive tests are rare. Change to a negative reaction is sometimes accompanied or followed by a recurrence of the vaginal discharge.

When a period of six months has elapsed after cessation of treatment without obtaining a 'positive' result (bacteriological or serological), or definite clinical evidence of vulvo vaginitis, there can in the opinion of the writers, be no object in continuing observation of the patient. Such continuous observation will tend to perpetuate anxiety in those responsible for the child, to keep up bad habits if they exist, and to fix in the memory an unfortunate experience.

### NON-GONOCOCCAL VULVO-VAGINITIS

This condition is not uncommon in girls between the ages of 2 and 7. It becomes relatively infrequent after that age, and appears to be very rare after the age of 10. The conditions which may give rise to vulvo vaginitis or are found in association with it, are of a very diverse character. They are as follows.

#### General Causes

It may develop as a prodromal symptom of the exanthemata—for example, of chicken-pox and measles—or as a sequela for example, of scarlet fever. It may occur during the course of general acute infections, particularly pneumonia and has also been observed in attacks of influenza and possibly in ordinary coryza.

It occasionally occurs in the course of general debilitating diseases and has been observed in the anaemias.

It may be secondary to acute throat infections most commonly streptococcal, it also occurs in association with cases of diphtheria and of Vincent's angina.

#### Local Causes

Foreign bodies—safety pins, marbles, gauze swabs, etc.—in the vagina.

Direct infection from fingers of mother, nurse etc., and by towels and clothing or by direct contact with dirt (as in children with inadequate clothing).

Secondary to irritation congestion, or inflammation in adjacent organs—for example, in association with thread worms, chronic constipation, appendicitis (acute or chronic) and infection of the renal tract.

Direct irritation of the parts by tight clothing or masturbation causes a local hyperaemia and predisposes to invasion of organisms. The tendency has also been noted in neglected children and in those especially difficult to keep clean—for example, spastic cases.

#### Clinical Signs

A differential diagnosis between the various types of vulvo vaginitis cannot be made without bacteriological tests but certain clinical signs are highly suggestive of certain causes. In diphtheroid infections for example redness of the vulva is present and discharge if present, is scanty. Discharge due to the presence of foreign bodies is characteristically blood

stained and offensive. *Staphylococci* usually produce a thick creamy discharge whilst that caused by the streptococcus is thinner and colourless. *B. coli* may give rise to an offensive discharge with a characteristic odour. The vaginal discharges which occur occasionally at the onset of a general infection may simulate any of the characteristic

### Bacteriological Diagnosis

The same precautions should be adopted in collecting material as in cases of gonococcal vulvo-vaginitis.

A large variety of organisms have been found in smears or cultures from vaginal discharge either singly or in combination. The relative frequency of the infecting organisms will very probably vary according to the centre at which a series of cases is studied. For example among seventy one cases examined at the Hospital for Sick Children Great Ormond Street by Dr Wood non-haemolytic streptococci (mostly enterococcus) were recovered from fifty one *B. coli* and a typical coliform bacillus from thirty six anaerobic Gram positive cocci *S. albus* and diphtheroids from a quarter to half the cases while the haemolytic streptococcus was isolated from ten and *S. aureus* from only two patients.

In fever hospitals the most frequent causal organism is the haemolytic streptococcus most of the infections developing as complications of scarlet fever or tonsillitis. Rarely *C. diphtheriae* produces a true diphtheria of the vagina although virulent strains may be present in the vagina without producing diphtheritic infection. Other organisms like the pneumococcus *H. influenzae* Gram negative cocci other than the gonococcus and the tubercle bacillus seem occasionally to be responsible for vulvo-vaginitis. *Trichomonas vaginalis* does not apparently produce infection in the child.

While organisms like the haemolytic streptococcus *S. aureus* and possibly *B. coli* which are known or potential pathogens do frequently initiate infection in a healthy vagina it is unlikely that saprophytic organisms like the enterococcus and diphtheroids do so and their predominance on culture may mean that they have supplanted or masked the original infecting organism. They may however perpetuate an infection arising from other causes.

An important point to which attention should be drawn is the very low infectivity of non-gonococcal vulvo-vaginitis. Familial spread is occasionally reported but epidemics of vulvo-vaginitis in schools and hospitals or indeed the infection of any one child by another appears to be very uncommon. The presence of a focus of sepsis (especially of the haemolytic streptococcus) obviously makes any child an undesirable occupant of a ward or dormitory but there is apparently little danger of the spread of vulvo-vaginitis as such.

### Treatment

The treatment of the non-gonococcal forms of vulvo-vaginitis calls for considerable judgment. Many of these cases are of a very mild character and require little or no treatment except baths and local cleanliness and removal of any causal factor. Indeed the great danger is over-treatment for prolonged swabbing and douching may not only keep up a vaginitis but actually increase it. Prolonged confinement to bed is very harmful; it lowers the general health and leads to masturbation.

The more severe infections should be treated on the same lines as the gonococcal cases including oestrin therapy. There are all grades between these severe cases and the patients with slight persistent discharge. Treatment varies therefore from simple bathing to the complete regime of the gonococcal case.

In a very small number of children the discharge proves extremely persistent and may fail to clear in twelve months or more. Suggestions are made for handling troublesome infections.

### Criteria of Cure

The great majority of cases clear completely after two to three weeks' treatment but it is advisable to keep observation on the child for two or three weeks after the discharge has ceased as recurrences are not unknown. In haemolytic streptococcal

infections the tendency to relapse may last for a considerable length of time.

In view of the alarm caused by any vaginal discharge children allowed to return to a residential school or institution should be examined at weekly or fortnightly intervals for two months after their return.

### ADMINISTRATIVE ASPECTS

This aspect of the problem is of great importance as any authority or organization undertaking the care of children sick or healthy is faced with two serious obligations: (a) to protect non-infected children from the possibility of infection with the disease and (b) to detect, isolate and treat any case of vulvo-vaginitis occurring in a child for whom it is responsible. The administrative measures found necessary to ensure these ends will vary greatly with local conditions and also as between children who are sick and those who are healthy.

For the protection of sick children the writers have suggested certain instructions which have with slight variation been in operation in the London County Council's hospitals for over two years. During this time no spread of the disease has occurred and it is felt that the precautions are adequate. The plan of swabbing all female children on admission to hospital was considered and rejected on the grounds (a) that the Council had such a large number of child patients that the procedure would be burdensome (b) that gonococcal infection is now shown to be extremely infrequent and (c) that it gives no real security and would in no way obviate the necessity for other precautions.

As regards healthy children in the Council's residential schools and receiving homes the staffs are asked to maintain a careful look out for any sign or symptom of the disease. The children's underclothing and bed linen are watched for evidence of discharge and any child considered suspicious is at once isolated and swabbed.

At residential establishments for healthy children the problem of isolation of a suspicious case presents greater difficulty than in a hospital. Many institutions have little or no provision for the accommodation of potentially dangerous material and the staff are naturally anxious to transfer any suspicious child as soon as possible. It has been found however that if too free encouragement is given for the transfer of girls to hospital children may be sent into hospitals quite unnecessarily for conditions which are more physiological incidents in development or for transient and quite unimportant redness of the parts. The handling and examination involved in taking a series of tests from any little girl must of course be undertaken without hesitation if necessary in the benefit of the child or her companion but it is not a light matter for obvious reasons. Experience has also shown that once a diagnosis of vulvo-vaginitis has been made even on the most slender grounds the child is marked out and her record is regarded with suspicion. Hence it is imperative that residential establishments should be certain that there is some definite evidence of vulvo-vaginitis before transferring a child to hospital for this condition. If however there is clinical evidence of vulvo-vaginitis is present an institution should not be expected to keep a child until bacteriological tests have been made and in no case should it be asked to keep a child who needs treatment.

It is the practice of the London County Council to concentrate in St. Margaret's Hospital all cases of vulvo-vaginitis in which a report of the presence of organisms morphologically resembling the gonococcus has been received. Further investigations to confirm the diagnosis are carried out after admission but in the meantime all possible precautions to non-infected children has been observed.

The article ends with a full summary and there are three detailed appendices: (I) The vagina in childhood; Dr R. Cruickshank; (II) Laboratory methods recommended for use in the identification of the infecting micro-organism; (III) Suggested instructions to staffs of hospitals and institutions.

## TUBERCULOSIS ASSOCIATION

## MEETING AT OXFORD

The annual provincial meeting of the Tuberculosis Association was held this month at Oxford under the presidency of Dr S ROODHOUSE GLOYNE

## Tuberculin Testing

On the first day Dr J HEIMBECK (Oslo), opening a discussion on the incidence of tuberculosis in young adults, said that in a survey he had conducted in Oslo he had found that at the age of 20 half the people were still tuberculin-negative. Among the nurses at the Ullevaal Hospital in Oslo all the probationers who were tuberculin-negative at the beginning of their training became positive before completing the three-year period. Among 284 nurses tuberculin-negative on entrance 104 developed tuberculosis, which proved fatal in thirteen. Among 668 tuberculin-positive entrants only thirty-four developed tuberculosis, and none died.

Dr H H BASHFORD (London) related his experience among the Post Office staff. The heaviest incidence of tuberculosis was found in the age group 20 to 30. Of all new cases of tuberculosis only half were ever able to return to work, and of these only a little more than half were working after a period of ten years. Dr C J C FAILL (Bristol) suggested that "summer time" tended to cause young people to play games until late at night, and therefore to make them unduly tired, lowering their resistance to tuberculosis. Dr PETER EDWARDS (Market Drayton) gave figures of tuberculin testing in the nursing and domestic staff at his sanatorium though small in number, they appeared to support those of Dr Heimbeck.

## Extrapleural Pneumothorax

On April 8 a discussion on extrapleural pneumothorax was opened by Mr R C BROCK (London). He had attempted this operation in fifty patients. In six the operation was abandoned owing to the presence of dense mediastinal adhesions, five had died, in the remainder a good collapse had been obtained. More experience was required in the selection of cases. He advocated extensive stripping of the parietal pleura, and then described a procedure he had introduced in which an extrapleural pneumothorax was joined to a lower intrapleural artificial pneumothorax by cautery division of the septum between them. Mr T H SELLORS (London) had also operated on fifty patients, two had died. In four patients tuberculosis developed in the opposite lung. He had also practised the procedure introduced by Mr Brock. When there were massive intrapleural adhesions he excised the area of the parietal pleura to which the adhesions were attached. He considered bleeding the chief complication. Mr TUDOR EDWARDS (London) had performed the extrapleural operation and division of the septum at the same time on fifteen occasions. He considered the results satisfactory. The post-operative management was discussed also by subsequent speakers. The second intercostal space inferiorly was recommended as the best approach for removal of the fluid which often forms in the extrapleural space. Dr L E HOUGHTON (Hendon) said that he was against too much stripping of the parietal pleura.

## Radiological Investigations

On April 9 the paper on progress in radiology, by Dr FELIX FLEISCHNER (Vienna), who was unable to be present, was read by Dr England. It was concerned mainly with Dr Fleischner's original work on atelectasis, and was illustrated with numerous beautiful skiagrams. He maintained that when a bronchus was blocked shrinkage of the lung distal to the block did not always occur, because other forces might keep it expanded. When this happened a transudate which filled the alveoli, developed after the air had become absorbed. There might be partial shrinkage together with an exudate. In these cases

the radiological shadow could be indistinguishable from that of a pneumonic process. Epituberculosis was a typical example of this condition.

Professor A E BARCLAY and Dr K J FRANKLIN (Oxford) gave the results of their recent investigations into the physiology of the lung. The work was done with a radio-opaque dust (so that cineradiograms could be taken) in cats. The cilia of the trachea and bronchi carried foreign bodies to the larynx spirally in a clockwise direction, when viewed from above, at a speed of from 1/2 to 3 cm a minute. Indian ink injected subpleurally was carried to the larynx in fourteen minutes. Dry dust or finely powdered lead glass when insufflated into the lungs never reached the alveoli, it was quickly eliminated from the tracheo-bronchial tree by the cilia. When moist, however, it rapidly lined the alveoli and did not disappear before many days.

## HEALTH OF THE ARMY IN 1936

Although the health of the soldier was satisfactory in 1936, there was an all-round increase in sickness incidence over that in 1935 and the preceding quinquennium, this is attributed in the latest Report on the Health of the Army<sup>1</sup> to abnormal conditions of service, more particularly in Palestine and Egypt. The admission rate showed an increase of 35.6 per 1,000 over that for 1935. In Egypt and Palestine combined there was an increase of 138.9 per 1,000, and in China 152 over that for the previous year. The diseases in the first two countries responsible for this large increase were sand-fly fever (27), diseases of the skin (18), tonsillar inflammations (153) and influenza (136), while "other diseases of the digestive system" (excluding tonsillitis, pharyngitis, gastritis, gastric ulcer, duodenal ulcer, and diseases of the liver) accounted for an increase of 28.7. Most of the sand fly fever occurred in Palestine, while in China influenza (48.9), venereal diseases (47.9), and malaria (28.5) accounted for more than 80 per cent of the increase. There were decreases in rheumatic fever and inflammation of the kidney, offset by increases in hysteria, middle-ear inflammation, pulmonary tuberculosis, epilepsy, valvular disease of the heart, effects of old injury, schizophrenia, duodenal ulcer and flat foot.

## Enteric Infections

In India the admission rate on account of the enteric group of fevers was the lowest yet recorded, this reduction having been effected in spite of an increased incidence of enteric infections in the civilian population. The notable improvement is partly ascribed to greater interest taken in child and family welfare by all Indian units, with the result that many hidden patients suffering from one of these fevers are now being efficiently treated thus eliminating an important source of infection. Moreover since the reduction of this incidence is very similar in both Egypt and India it would seem that the improvement is partly due to introduction of the new TAB vaccine supplied for preventive inoculation by the Royal Army Medical College and the Central Research Institute Kasauli. In India also the number of admissions for dysentery in 1936 was less by 253 than in the previous year, but in Egypt and Palestine there was an increase of 260 partly due to a larger number of troops living for the most part under active service conditions. There were no waves in the incidence in Egypt one in April and the other in November, which were consequent on and ran parallel with the periods of greatest fly prevalence. The dysentery reported from stations at home was without exception a recurrent or an infection contracted abroad. Reports show that the treatment of bacillary dysentery combined with the use of serum where necessary, is universally satisfactory. In Egypt a few cases were treated with bacteriophage with good results but the number treated was too small to permit any useful comparison. Compared with 1935 the clinical group was reduced by 111 which indicates an improved liaison between

<sup>1</sup> H.M. Stationery Office 3s., postage extra

the hospitals and the laboratories but it is remarked that in certain stations abroad the laboratory is situated at a considerable distance from the hospital and that it is this long distance factor which tends to prevent the isolation of the causative organism from the stools. There were only two admissions for amoebic abscess of the liver both of which responded well to emetine treatment.

### Malaria

In India an increased incidence of malaria was reported in the Northern Command and the Burma District with general decreases elsewhere though the climatic conditions favoured the spread of this disease. Its increase in the Northern Command was an aftermath of the Mohmand operations of 1935. During these operations delay action quinine was given to the men in camps which were notoriously malarious. While this had the effect of keeping the men at duty it reacted by producing a larger number of relapse cases and latent fresh infections during the following spring. In addition the breeding season of the Rawalpindi District extended into late November with many admissions during that month. Multan is now the most malarious district its admission rate in 1936 being 176 per 1,000; the reason for this is held to be the changed climatic conditions—increases in humidity and rain fall having become apparent in the areas affected by the new irrigation from the River Indus. Malaria in Delhi was further reduced from 87.5 per 1,000 in 1935 to 71.6 per 1,000 in 1936 in consequence of intensive anti-malarial measures in both civil and military areas in the city. The relapse rate for all India during 1936 was almost half that for 1932 but in the Northern and Western Commands the relapse rate was much higher than in 1935.

### Research Investigations

The situation in Egypt and Palestine in 1936 afforded an opportunity of observing to some extent the protective value of the recently modified typhoid vaccine. Since the strength of troops in these Commands had been almost doubled an increased incidence of typhoid fever was expected. Not only did this not occur however but the case rate for the enteric group of infections was only 0.4 per 1,000 compared with 1.7 in 1931. On the other hand the incidence of these infections among the civil populations in Egypt showed a gradual increase due most probably to improved methods of diagnosis. The year 1936 was considered a bad year for civilians. It would therefore seem that the incidence of these diseases in the Army was favourably affected by the introduction of the recently modified vaccine. The Army Pathology Advisory Committee met in June 1936 when the arrangements for the pathology services of the Army were reviewed and consideration was given to the provision of tetanus antitoxin, leptospirosis in the Army in England, the laboratory diagnosis of glandular fever and the investigation of an influenza epidemic in the Eastern Command. Co-operation with the workers of the Medical Research Council continued including an important trial of the new mouse virus vaccine, a study of the mannitol group of dysenteric organisms and of water purification in the field. Sodium mandelate with ammonium chloride in the treatment of urinary infections due to *B. coli* gave very satisfactory results on clinical trial. Evipanodium gave satisfaction as the anaesthetic for ear, nose and throat surgery, except in enucleation of the tonsils some cases of which showed a tendency to haemorrhage. Specially prepared ascorbic acid tablets were analysed and found to be adequate for the prevention and cure of scurvy.

### Medical Examination of Recruits

In consequence of a falling off in the number of recruits during recent years a War Office committee assembled in May, 1936 to inquire generally into the causes of rejection of prospective recruits to examine the then existing physical standards, and consider the possibility of taking into the Army men below the agreed standards who in the opinion of the medical authorities might reach those standards after a period of special training. The committee agreed that the standards of general health and physique should not be modified

but that the introduction of mechanization and the increase of specialization would permit of an adaptation of certain standards to conform with these conditions. Accordingly the Army was classified for recruiting purposes as (1) the hereditary and foot class (2) mechanized class (3) M.T. class and (4) L or C class. A medical subcommittee then drew up modified physical standards to accord with this classification and it is calculated that when they came into operation on December 1, 1936 there was a saving of 216 recruits, 12.4 per cent of the total in the remaining months of that year. A preliminary experiment limited to men below the standards of weight and/or chest measurement and those suffering from functional defects of the heart was undertaken at the Army School of Physical Training, Aldershot during the last three months of 1936. Of the thirty-three men enlisted twenty-four attained the necessary standard and were drafted for duty in depot sections who only just failed to reach them were subsequently drafted and only two were finally rejected. A special centre was subsequently established for the reconditioning of recruits of this type. A proposal was also put forward for the admission of recruits who were up to standard and in all respects except for some curable defect such as varicose veins or enlarged tonsils and to admit them to hospital for treatment; this was approved.

## Nova et Vetera

### THE EARLIEST ENGLISH PRINTED MEDICAL TREATISE, AND OTHERS

Hard upon the dispersal of the medical books belonging to 'Sion College' comes the announcement of the sale of Sotheby's on May 20 and 21 of an older and no doubt though smaller collection, the historic and superb library from Ham House Surrey. In passing it may be mentioned that the gem of the Sion books Harvey's *De Motu Sanguinis* (first edition) turned out to be in somewhat deteriorated condition and so fetched only £238, probably less than half of what a good copy would have realized. The Ham House library was formed mainly by the first Earl of Lauderdale, his son the first Duke of Lauderdale, the latter's stepson the third Earl of Dysart and chief by the fourth Earl of Dysart who although unpopular with some of his contemporaries had a very distinguished taste in fine and beautiful books. The presence of such a Caxtons is enough to make the mouth of every collector water to say nothing of several of the products of Wynne de Worde and Pynson many of them of the greatest rarity.

The few medical books are of the highest interest and in one or two cases have as well great association value. Particularly is this true of the first edition in French of the *Ortus Sanitatis* printed on vellum in Paris in two volumes about 1400 and specially illuminated in gold and colours by Antoine Verard for Henry VII with the latter's arms. The auctioneers have traced a payment in the royal account books for 1502 of £6 for two books called the garden of health but they state that Verard's price for a vellum copy such as this would be many times higher and there is no evidence that it ever came into the King's possession as throughout the sixteenth century it appears to have belonged to the Landgraves of Hesse; moreover the paper copy bought in 1502 is not actually in the British Museum. It is possibly illustrated mainly with woodcuts or plans but there is a large picture of a human skeleton.

### "The Governable of Helth"

The earliest medical work printed in the English language and the first medical work printed in England is the *Governable of Helth* *Medicina Sancti* published in 1489 by William Caxton, one of our earliest known authors and that is in the Bodleian Library. It is hard to

## Reports of Societies

### PSYCHOLOGY AND GYNAECOLOGY

At a meeting of the Medical Society of Individual Psychology on April 7, with Dr H C SQUIRES in the chair, Mr ALECK BOURNE read a paper on psychological conditions underlying gynaecological symptoms.

Mr Bourne said that one of the most important aspects of clinical medicine was the differentiation of organic diseases from those due to disturbed function. Undue emphasis in the teaching of students was placed on established and even terminal organic conditions, while the clinical states due to disturbed function were often neglected. Disturbed function of the pelvic organs as in other parts of the body, might be due to a habit of life, to prolonged emotional stresses, or endocrine imbalance. Physical signs in adolescent girls, which were almost certainly due to over-stimulation by oestrin, included excessive non-infective leucorrhoea, highly acid vaginal secretions, a high content of epithelial glycogen non-infective erosion, and a soft, easily dilatable internal os uteri. He had coined the word "oestrosis" to describe this syndrome. The question of interest to psychologists was whether the excessive oestrin production was primary or secondary to a mental state arising from sexual maladjustment.

### PROGESTERONE THERAPY

A meeting of the Aberdeen Medico Chirurgical Society was held on April 7, with the president, Dr H E SMITH in the chair, when Dr SUSAN PATERSON (Edinburgh) gave an address on the therapeutic uses of progesterone.

Dr Paterson outlined the current view of the hormonal control of the menstrual cycle and pregnancy, and concluded that the corpus luteum hormone, progesterone, was essential for the maintenance of pregnancy. Its functions were to prepare the endometrium for the embedding of the ovum, to inhibit normal uterine contractions and further ovulation, and to lessen the sensitivity of uterine muscle to pitocin. After dealing briefly with the method of standardization and the dosage, and emphasizing that corpus luteum preparations were inert when given by mouth, she described the gynaecological and obstetrical indications for their use. Under the former heading came certain functional uterine haemorrhages and certain cases of dysmenorrhoea. The former occurred much more frequently from an oestrin stimulated type of endometrium than from a progestational endometrium, suggesting at once the use of progesterone. Pubescent haemorrhages in 80 per cent of cases were non-ovular, and the bleeding might be dangerous, progesterone was eminently satisfactory in tiding the patient over the danger period until normal ovulation occurs and the bleedings cease. Dr Paterson described two personal cases, treated with complete success with 1 mg daily until the bleeding stopped. In metropathia haemorrhagica treatment by a menopausal dose of radium, after diagnostic curettage, was advocated. Dysmenorrhoea due to forceful muscular contractions of a normally developed uterus, subject to uninhibited oestrin sensitivity to posterior pituitary, might logically be treated by corpus luteum. It was characterized clinically by uterine colic starting before the flow and continuing through the first or first and second days of the flow and also, usually, by a rather prolonged and profuse period. Two cases were treated by 2 mg progesterone on the seventh, fifth and third days preceding the period with a good immediate result in each case, but it had not been possible to follow them up.

### Obstetrical Uses of Progesterone

The obstetrical conditions in which corpus luteum had been used included sterility, threatened abortion, habitual abortion after pains, and pre-eclampsia. In sterility

imagine a more desirable acquisition for a medical library than this magnificent folio Bartholomew Glanville's *De Proprietatibus Rerum* Wynkyn de Worde, 1495, is the first book ever printed on paper made in England (at Hertford) this Ham House copy unfortunately lacks five leaves. The first quarto edition of Sir Thomas Elyot's *Castel of Helth* Berthelet 1541 is bound in with Thomas Paynel's translation of the *Regimen Sanitatis Salerni* (same publisher and year) and with the first quarto edition of a book whose full title is *Of the Wood called Guaiacum that healeth the frenche pockes and also helpeth the goutte in the feet the stone pulseve lepie dropsy fallinge euyl and other diseases* made in latyn by Ulrich Hutten Knyght and translated into englysh by Thomas Paynel, Berthelet 1540. Elyot's book first appeared in 1539 in octavo, and Hutten's, too had been previously printed in that form. There is also a Latin copy of Hutten's work *De Guaiaci Medicina et Morbo Gallico* printed at Mainz by Schoeffer in 1531. Bound up with three other non-medical works is Walter Carys *Hammer for the Stone* so named for that it sheweth the most excellent remedie that ever was known for the same, John Windet, 1586. A curiosity is the translation into English verse of Christopher Balistas *Overthrow of the Gout* written originally in Latin verse. The translation is by B G, thought to be possibly Barnaby Googe. It is dedicated to Richard Master, physician to Queen Elizabeth and was published by Abraham Veale in 1577.

### Three Treatises Bound Together

Elizabeth Blackwell's *Herbal* 1739, of which a copy is offered, is naturally overshadowed in importance by a volume which contains three medical treatises bound together they are *The Grete Herball whiche geneth parfyt knowlege and understanding of all manner of herbes and there gracyous vertues also the noble experiens of the vertuous handwarke of Surgery* Southwark, Peter Treveris 1526, Jerome of Brunswick's *Vertuous boke of the distyllacyon of all manner of herbes newly translate out of Duuche into Englysshe* Andrewes, 1527 and the same author's textbook of surgery, with woodcuts of surgical instruments, Southwark, 1525. The only remaining medical book is a French treatise by Charas, 1670, on vipers and remedies for their bites.

### ANNALS OF MEDICAL HISTORY

Of the seven main articles of the second instalment of *Annals of Medical History* for this year three deal with medicine in Virginia and are continued and concluded from the previous number. The memoir of Hunter Holmes McGuire of Richmond Virginia shows the active part which he played in the North and South War and that he was primarily a great physician and incidentally a safe and conservative surgeon, thus illustrating Nicolas Senn's dictum that a good surgeon is a good physician who operates and recalling a somewhat similar aphorism of the late Lord Moynihan. The article on Pioneer Medicine in Virginia contains an account of the tropical work of Walter Reed and of M R Carter on yellow fever. Dr Joseph Kriska describes the Torv Doctors of Georgia under the Britishment Act of 1778. The other articles include a concise sketch of the part played by the Jewish physician in the progress of his people by Dr H A Savitz of Boston, Miss Alice Willcox's collection of medical references in the dramas of John Lyly who spoke of tobacco as our holly hearbe Nicotina and recommended its use in a salve with cooling violets and honey to heal a wound. F T Gardner and C D Lake of San Francisco reproduce with their comments the letter on the usefulness of oliginous warm baths sent by Dr Browne Langrish of Petersfield to the Royal Society in 1747.

*Annals of Medical History* New series vol x No 2 March 1938. Edited by Francis R Pickard M.D. (Pp 107-196 illustrated. Subscription for year 11 dollars single number 2.50 dollars.) New York: Paul B Hoeber Inc. London: Book Department at Harper and Brothers. 1938.

where curettage immediately before a period revealed an endometrium with slight progestational changes but changes not proportional to the time in the cycle treatment by progesterone might be tried in the week of the cycle preceding menstruation with the idea of making the endometrium suitable for nidation. In threatened abortion there was no doubt of the efficacy of progesterone. It acted probably in inhibiting contractions of the uterus and if such contractions had proceeded far enough to cause some haemorrhage comparatively large doses were required—Schering suggested 5 mg on five consecutive days. There was little doubt that habitual abortion was due to lack of corpus luteum hormone but that a deficiency of this hormone was due to a deficiency of vitamin E as Young suggested remained to be proved. Dr Paterson had had five successful cases out of six using 2 mg weekly throughout the first four months with increase to 5 mg at the week of the suppressed menstrual periods and with 5 mg daily for three days if there were haemorrhage or downbearing pains. In sixty-five cases in the literature fifty-seven were successful—88 per cent. Although in the majority of patients after pains could be rapidly relieved by injection of 1 mg progesterone the advisability of suppressing these pains was open to question.

### Pre-eclamptic Toxaemia

Thirty cases of pre-eclampsia had been treated to date with progesterone most of them being severe cases. Care was taken to exclude nephritis. Treatment was restricted essentially to the administration of progesterone but the following basic precautions were taken: (1) a balanced diet of approximately 1650 calories was given, not salt free and not protein free but excluding red meat; (2) in all cases where oedema was marked fluid intake was restricted to less than 40 oz until the fluid output was greater than the intake; (3) when headache was severe luminal was given. Progesterone was given intramuscularly in 5 mg doses daily for the first three or four days and thereafter depending on response, at longer intervals. In certain cases where no response was noted after one day 10 mg were given on the second, third and fourth days. All cases recovered and only one mother developed fits after treatment had started and that on the second day. The following table compares results in severe cases in the year before progesterone was used and in the following year in which it was used.

	Conservative (31)	Progesterone (22)
Developing fits	10	1
Maternal mortality	3	0
Foetal mortality	10	7
Corrected foetal mortality	10 (32%)	5 (17%)

The theory underlying the use of corpus luteum hormone in pre-eclamptic toxaemia was suggested by Robson's experiments on rabbits which seemed to prove that the health of the placenta depended on the health of the corpus luteum and that toxaemia was the direct result of a placenta no longer healthy. Dr Paterson said in conclusion that treatment by progesterone was a substitution therapy; it would not revivify areas of placenta damaged past repair, but it would help to maintain the health of the part of the placenta still functioning. Obviously the earlier the deficiency of corpus luteum was recognized and the corrected the better would be the results and in severe cases of pre-eclampsia conservative measures (rest in bed, attention to bowels, etc.) were necessary to deal with the toxins in circulation. It is this theory was sound it followed that if patients with the earliest signs of pre-eclamptic toxaemia were treated with this form of therapy eclampsia could be practically eliminated as a dangerous complication of pregnancy.

Professor BAIRD expressed surprise at the high percentage of successes with progesterone in habitual abortion. With regard to pre-eclampsia sixty-five cases had been treated without progesterone at Aberdeen Maternity Hospital in 1937 with no maternal deaths and eight foetal

deaths. These results were as good as those achieved by progesterone. If progesterone were to be employed it would probably be most useful at the sixth month in cases with early rise of blood pressure and without albuminuria. Mr GEORGE DAVIDSON, dealing with habitual abortion, questioned the theoretical basis of the principle of giving increased corpus luteum at the time of the suppressed menstrual period. Dr PATERSON in reply stated that this was done not on theoretical grounds but because clinical experience showed that abortion was most likely to happen at the time of the second and third suppressed period.

### SURGERY OF DUODENAL ULCER

At the March meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland with the president Mr A. A. McCONNELL in the chair Mr GARNETT WRIGHT (Manchester) read a paper on surgery and the duodenal ulcer.

Mr Wright began by discussing no different phases through which the surgical treatment of duodenal ulcer had passed during the present century, mentioning finally the dispute into which the operation of gastro-enterostomy for non-stenosing cases had fallen and the recent tendency to replace this operation by partial gastrectomy. He then proceeded to review his own experience of 145 cases treated at the Salford Royal Infirmary, gastro-enterostomy had been carried out in 137. There were three deaths in this series—a mortality of about 2.2 per cent—and ninety-four of the survivors had been traced. Of these about 80 per cent were either quite well or much improved but the incidence of secondary ulcers was rather high, occurring in nine cases altogether, of which four were proved at operation while in the remaining five the presence of a secondary ulcer was surmised on account of either haemorrhage or radiological evidence. In a small series of cases treated medically the results were almost the same as in those cases submitted to gastro-enterostomy—namely about 75 per cent of successes. In spite of the high incidence of secondary ulcers Mr Wright made a strong plea for the operation of gastro-enterostomy since it gave such a high proportion of successful results with a comparatively low mortality and in a comparatively short period of time—an important point in the hospital patient. Gastric ulcer except in the hands of a few experts was associated with a much higher mortality and furthermore did not necessarily prevent the development of secondary ulcers.

Mr Wright further stated that in his hands the after results of such operations as pyloroplasty had not been nearly so satisfactory as those of gastro-enterostomy.

### General Discussion

Mr SETON PRINGLE said that of recent years he had adopted purely medical treatment in uncomplicated cases. Surgery might be necessary in cases which did not yield to medical treatment or for patients who could not tolerate economic results. Following the necessary regime in such patients he did a gastro-enterostomy provided the gastric acidity was moderate and the acidity was high he preferred a partial gastrectomy. In cases complicated by stenosis he believed that gastro-enterostomy was all that was required, cases of haematemesis he treated conservatively.

Professor HENRY MOORE said that about 75 per cent of non-stenosing ulcers could be cured by medical treatment. A course of medical treatment both before and after operation was highly desirable and might be an important factor in the avoidance of secondary ulceration. He had found that if patients with this disease were treated medically Mr HARRY MEADE said that in cases with stenosis he carried out a gastro-enterostomy and in cases without stenosis he carried out a gastro-enterostomy unless the ulcer was eroded. Professor W. S. SARGE said that the importance of realizing that the cause of duodenal ulcer was not known, there were a number of treatments all of which were fairly successful.

## RECENT ADVANCES IN RHEUMATISM

At a meeting of the West London Medico-Chirurgical Society on April 8, with Dr D G RICE-ONLEY the president, in the chair, a discussion took place on recent advances in rheumatism

Dr J F HALLS-DALLY submitted that rheumatism should be regarded as a series of variable and often interchangeable syndromes. The classification he suggested was (1) acute or subacute rheumatism, (2) chronic non-specific arthritis, which included (a) rheumatoid arthritis (atrophic) and (b) osteo-arthritis (hypertrophic), and (3) non-articular forms. Acute rheumatism had certain constitutional peculiarities. Untreated, it was a self-limited malady. If treated in the accepted fashion with salicylates, it yielded to these far more readily than did any other condition in the rheumatic group. Moreover, it was not exclusively an affection of the heart, of the joints, or of the nervous system, for at any time it was capable of involving any of these structures. The real explanation of the similarities between acute rheumatism and rheumatoid arthritis might be found in the assumption that the type of reaction of the body tissues to infection depended on the formation in the blood—not in the tissues—of sufficient antibodies. If these were present in adequate numbers rheumatic fever cleared up, but if there had been insufficient antibody formation, transition into a state indistinguishable from rheumatoid arthritis took place. Rheumatic infection and rheumatoid arthritis were thus more related to one another, as representing variations based on a similar aetiology, than to osteo-arthritis, which he placed in a separate category. Though something was known of the basic as well as of the contributory factors in rheumatism, little was known, and nothing definite had been proved, as to the infective factors. The speaker reviewed the position of research in relation to rheumatoid arthritis and osteo-arthritis. A biochemical investigation of the urine in his experience was of great value in dividing all cases of chronic rheumatism into two main metabolic types. The alkaline urinary or metabolic deficiency type was related to rheumatoid arthritis, and the acid or metabolic excess type to osteo-arthritis or arthrosis. He discussed briefly preventive, general, and special treatment.

## Methods of Treatment

Dr W S C COPEMAN showed a cinematograph film illustrating the typical appearances in chronic rheumatism, with some indications of the technique and results of treatment. Discussing modern advances in treatment, Dr Copeman placed first physical medicine, and after this gold treatment, which in its limited sphere in rheumatoid arthritis was a major advance. Next came the serial plaster treatment of rheumatoid arthritis, originating from Boston then the postural methods of Goldthwait and Osgood, manipulations, and finally the injection of novocain and saline into the tender areas of fibrositis to which pain was referred. The history of the organization of the treatment of rheumatism, he said, was recent, not really starting until 1930, when the British Red Cross Society opened its clinic in London. Three years later the Minister of Health allowed physical treatment as an additional benefit under the National Health Insurance Act at approved centres, but to-day there were only three such centres—in London, Sheffield, and Aberdeen.

Dr C B DYSON introduced the subject of the serology of acute rheumatism. He described the bacteriology of rheumatoid arthritis as a 'complete fog.' In about 85 per cent of all cases of rheumatoid arthritis there were agglutinins to a significant titre for the haemolytic streptococcus and yet in these cases the streptococcus was not found as a significant infection. But even if the organism was a secondary invader its presence could do much harm and its removal much good to the patient. The complications of measles to take a parallel example, were not due to the primary virus but to the secondary invaders.

## Local News

## ENGLAND AND WALES

## Hospitals Day, 1938

The combined hospital flag days in London for 1937 produced a grand total of £32,569, representing an increase on the total annual income which the hospitals concerned used to derive from their individual flag days. When the plan was first started, at the suggestion of the Chief Commissioner of Police for the Metropolis, seventy seven hospitals joined in, and 108 participated during 1937. This year 135 hospitals are combining. While the special hospitals are to collect in October, the other hospitals will make their collection on Tuesday, May 10, in Inner London and on Saturday, May 14, in the outlying areas. Already Lord Luke, chairman of the London Hospitals Street Collections, has received promises of help from local public authorities situated in the Metropolitan Police District, Messrs W H Smith and Sons, many cinema theatres, hotels, business houses, markets, and the main railway companies. All suggestions and offers of service should be sent to Lord Luke at the headquarters of the Central Committee, 36, Kingsway, WC2.

## Central Midwives Board

At the April meeting of the Central Midwives Board for England and Wales it was announced that Sir Comyns Berkeley, M.D., F.R.C.P., F.R.C.S., had been unanimously re-elected chairman for the year ending March 31, 1939. The vacancy in the membership of the Board has been filled by the appointment of Miss G A B Cameron (public health department, Newcastle upon-Tyne). The remainder of the Board, all of whom have been re-appointed until March 31, 1939, consists of Councillor R W Brosch, J G Buchan, M.D., Miss K V B Conn, W Allen Daley, M.D., D.P.H., Mr H A de Montmorency, Miss E E Greaves, Eardley Holland, M.D., F.R.C.S., F.R.C.P., Miss A A I Pollard, Lady Richmond, Miss K J Stephenson, and Arnold Walker, M.B., F.R.C.S. With regard to the question of examination under the new training and examination rules of the Board it was resolved that the first examination under the new rules, which is, to all interests and purposes, the same as the examination under the existing rules, should be conducted by doctors as at present, but that, having regard to the nature and object of the second examination under the new rules, such examination should be conducted jointly by doctors and State certified midwives.

## Orthopaedic Clinics for Yorkshire

A meeting was held recently at the General Infirmary at Leeds to forward the work of the Yorkshire Association for the Care of Cripples. Commander Henderson, of the Wingfield-Morris Orthopaedic Hospital, Headington, near Oxford, dwelt on the need for early treatment of all orthopaedic cases, and said that by the establishment of local clinics a large number of patients could receive skilled treatment without necessarily entering a hospital as in-patients or having to make long journeys for out-patient attendance. It was a great advantage to the patient and to the hospital that surgeons and nurses should visit the smaller towns and rural areas instead of the patients all crowding into one building at stated hours for special treatment. The clinics were in effect scattered out-patient departments of the hospital, but, not being concentrated in one building, they could widen the scope of their work. Miss Miller, organizing secretary of the Yorkshire Association for the Care of Cripples, outlined the work it hoped to do in the county by extensions to existing hospitals.

and the establishment of associated after care clinics. The next step would be to build another orthopaedic hospital in the south of the West Riding, and to found a training college for the whole of Yorkshire. Dr J. Johnstone, Jervis medical officer of health for Leeds, said that the enlarged Thorp Arch Orthopaedic Hospital when completed would be the hub of a system the spokes radiating into all parts of the county.

### LCC Hospital Expenditure

The estimated expenditure on the hospital services of the London County Council in the year 1935-6 is £630,981, and the estimated income £536,625. The proposals which have already been approved for the further development of the consultant and specialist service at the hospitals involve an increase of about £20,000. The total cost of this service is upwards of £40,000 a year. The new domiciliary midwifery service accounts for an increase of about £41,000 in the estimates and increased charges for tuberculous patients account for £22,000.

### Recognition of LCC Hospitals

More than a year ago the Royal College of Surgeons of England agreed to recognize sixteen of the general hospitals of the London County Council for the purpose of qualification for admission to the final examination for the Fellowship of the College. The same hospitals have now been recognized by the Examining Board in England set up by the Royal College of Physicians of London and the Royal College of Surgeons of England for the purpose of the regulations for obtaining the Diploma in Anaesthetics (D.A., R.C.P. and S. Eng.). In addition seven more of the council's general hospitals making a total of eighteen have been granted recognition by the British College of Obstetricians and Gynaecologists as establishments at which the medical staff may qualify for candidature for the Diploma or Membership of the College.

### Leprosy in the British Empire

The annual general meeting of the British Empire Leprosy Relief Association took place at the India Office with Viscount Halifax in the chair on April 26. Sir William Peel, chairman of the executive committee in presenting the annual report for 1937 said that there were to-day at least two million lepers in the British Empire and in spite of the combined efforts of local governments, missionary bodies and the Relief Association which worked in co-operation with the H. V. H. little had been achieved in checking the incidence. In some colonies it was believed to be tending to increase. Even in colonies where much was being done to care for and treat the leper little had been achieved in regard to prevention. Some of the more prosperous colonies such as Malaya and with the association's help Nigeria were doing a great deal to combat the disease. In Hong Kong progress had been retarded owing to economic conditions. Valuable research work was being carried out at Calcutta in co-operation with the School of Tropical Medicine and the Indian Research Fund Association under the direction of Dr John Lowe. In Madras alone during the first nine months of last year there were nearly 600,000 attendances for treatment at the various centres. Sir Cuthbert Sprawson, retired Major General I.M.S., a new member of the executive committee gave an address in which he enlarged on the necessity for educating the public including the public of the country whose natives suffered from leprosy. The people in those countries he said might be uncultured and ignorant but they had sufficient natural common sense to understand the nature of the danger when it was explained to them and to appreciate the good intentions of the association's workers. It was interesting in the same connexion to consider how leprosy disappeared from England in Plantagenet and Tudor times. Various factors were concerned no doubt but the principal one he thought was the great interest

in leprosy which then existed among all sections of the population. This was shown in the establishment of about 200 leper hospitals in an age when hospitals were not common institutions. It was plain that the whole country was aroused and set itself upon a leprosy campaign attaining a surprising success when the deficient knowledge and lack of personal hygiene were considered. It was important now to arouse an interest of this nature throughout the affected parts of the Empire and the mother country. Sir Cuthbert described his experience in conducting a leprosy campaign in the Madras Presidency and the need for the enlistment of enthusiastic social workers some of them perhaps recovered patients who were able to demonstrate to the affected people that someone was taking an interest in them and so encourage them to co-operate in the necessary measures for their own good and the good of the community. Leprosy had raged in some places for so long that there already existed a tribal tradition and an understanding though imperfect as to what should be done. In the Laccadive Islands and in the Island of Minico the lepers were in a voluntary segregation sent to one end of the island on a peninsula where they lived happily in their manual occupations. It was necessary to foster such native public opinion in all infected countries and to organize it on proper lines. It was not within the power of the association to do it directly among large bodies of people but by approaching the governments it should be possible to secure that the desired propaganda was conveyed to all natives.

## SCOTLAND

### Edinburgh Orthopaedic Clinic

At the annual meeting on April 4 of the Edinburgh Orthopaedic Clinic Mr Robert I. Stirling said that this clinic started in 1926 and was formally constituted in 1931 for the benefit of people with limited incomes who required massage, ultra-violet ray treatment and other forms of physiotherapy but who were unwilling to avail themselves of free service in hospitals. The clinic was first started especially for the benefit of such persons who were capable of continuing their employment if treatment could be given after working hours. Some of the patients suffered from rheumatism, some came to the clinic after domestic or industrial accidents or after operations, many came with early static or postural irregularities for which successful preventive measures were of great economic importance. In some instances where the patient could not attend the clinic treatment was carried out in his home. The report showed that during the past year 605 patients had started treatment and 10,296 treatments had been given. Forty-eight patients had been visited during the year, including 917 visits. After-care involving 1,222 treatments had been given to thirty-six patients from the Princess Margaret Ross Hospital for Crippled Children. The clinic's existing premises were proving too small for the steady increase in the number of patients and the committee was at present considering the acquisition of new and larger accommodation.

### Prevention of Blindness

The W. H. Ross Foundation for the Study of the Prevention of Blindness was opened on April 20 at 20 Lauriston Place, Edinburgh, by Mr W. S. Douglas, Secretary to the Department of Health for Scotland. Mr Ross, who has succeeded to the total blindness fund since his eyesight failed in 1923, has endowed this research foundation at a cost of £20,000. In 1937 he deposited his sum with interest at the Bank of Scotland, which as well as the interest from an endowment was to be applied to the furtherance of investigations into the causes of blindness. Dr A. H. H. Sinclair, the

man of the trustees, said that they would not only investigate the prevention of actual blindness but would study all forms of deterioration of sight and the enhancement of the visual function. Investigations were already in progress which had entailed the examination of 700 coal miners and 200 shale miners, and work was proceeding with reference to glaucoma. The work was dependent on collaboration of the practitioners of Edinburgh and the good will of ophthalmologists throughout Scotland, and valuable help had been obtained from the staff of the eye department of the Royal Infirmary. It was hoped that Glasgow and other leading ophthalmic centres would eventually give practical help to this cause. The Department of Health for Scotland was also helping in regard to statistics of the causes of blindness. Professor A. J. Ballantyne, Glasgow, said that individual effort could not solve ophthalmological problems, which offered a very wide field for organized research, and the Ross Foundation would find its greatest sphere of usefulness in team work.

#### Aberdeen Medical Curriculum

The General Council of the University of Aberdeen, at a meeting on April 16, gave general approval to a proposal by the Senatus to add two terms to the present curriculum, thus extending it to seventeen terms. The draft of the new curriculum, which still remains to be adjusted in details, assumes that all students will start medical study at the beginning of the winter term, and in the final year certain special classes will extend over the summer vacation. Dr. Thomas Fraser, in moving general approval of the draft scheme, expressed the hope that the important question of extra-mural teaching would be considered, and he appealed for more attention to child welfare. He also considered that three and a half months' holiday in the summer vacation was too long, and that some of this time might be spent in hospital under supervision. Professor Campbell referred to arrangements that had been made for having a students' residence in the hospital centre at Forresterhill so that the students might take full advantage of clinical instruction in the various hospitals which had been erected there under the joint hospitals scheme.

#### Fife Medical Officer of Health

The staffing committee of the Fife County Council has appointed Dr. George Matthew Fyfe as medical officer for the county to succeed Dr. Pratt Yule, who is retiring. Dr. Fyfe graduated M.B., Ch.B. at Aberdeen University in 1920, and took the D.P.H. in 1925. For some three years he acted as a Carnegie research assistant in the physiology department of the University, and as assistant medical officer in the clinic to the Ministry of Pensions at Aberdeen. In 1923 he was appointed assistant medical officer of health for Aberdeen, and organized a clinic at the City Fever Hospital. Three years later he became medical officer of health for St. Andrews and bacteriologist to the James Mackenzie Institute for Clinical Research. Following changes under the Local Government (Scotland) Act 1929, he became in 1930 a deputy medical officer of health for the county of Fife, a post which he still holds.

#### "Neo-Hippocratism"

Dr. P. K. McCowan, physician-superintendent of the Crichton Royal Institution, Dumfries, states in his annual report that the doctrine of neo-hippocratism, or constitutional medicine, has been permeating medical practice during the last twenty or thirty years, and is a return to the basic principles laid down by Hippocrates, with his emphasis on the constitution of the individual patient, including his mental and physical make-up. Neo-hippocratism asserted that we could no longer regard the cells, tissues and organs of the body as separate units, the real biological unit being the individual. Physiology, with its chemical integration through the endocrines and its

nervous integration through the vegetative and central nervous system, had already shown that any smaller unit was an abstraction. Even in the most apparently local disease there was a disturbance through the whole individual, with biochemical changes in the fluids, changes in the nervous system, and psychical changes. These were not merely evidence of disease, but represented the result of a struggle in which the patient mobilized all his resources. The mere diagnosis of disease was therefore not sufficient, but a thorough knowledge of the body and mind of the patient was a necessary preliminary to treatment. To be consistent, treatment should agree with the constitutional principle, aiming at helping the patient's constitution in its struggle. In psychiatry the methods available to help the physical or mental resources of the patient included psychotherapy, physical medicine, heliotherapy, diet, occupation and recreation, endocrinology, and the judicious use of sedative drugs and of drugs acting on the sympathetic nervous system. All these methods of treatment would repay further research. Throughout the history of medicine two principles of treatment were found to crop up in connexion with little-understood diseases—the nihilistic and the chirocistic. The former favoured a negative policy, leaving everything to nature, and was very popular in the mid-nineteenth century, on the basis that curable diseases, if left to run their course, were likely to improve in the absence of needless meddling. The chirocistic principle—called after Chirac, a French physician of the eighteenth century—consisted of excessive intervention, which took the form of repeated bleeding, excessive purgation, and the use of strong drugs; it was the very antithesis of modern constitutional medicine. They must be careful not to transgress the constitutional principle in psychiatric practice, and unless such forms of treatment as hypoglycaemic shock and fits induced by cardiazol in the treatment of schizophrenia were ultimately shown to be in accordance with this principle, their present popularity was likely to be short-lived. It had been found that kindness and individual attention were preferable to fear in the education of the young, and this psychological lesson was equally important in psychiatry.

#### Edinburgh Postgraduate Courses

The syllabus of the postgraduate courses in medicine to be held in Edinburgh during the summer contains particulars of the instruction obtainable in July, August, and September. From July 11 to 29 there will be a course in obstetrics and gynaecology at the Royal Maternity Hospital and the gynaecological wards of the Royal Infirmary, fee £10 10s. A general practitioners' course will be held from August 15 to September 10, fee £10 10s for four weeks or £6 6s for two weeks. A general surgical course will be held concurrently at the same fees. An eight-weeks course on internal medicine will be held from October 17 to December 10, fee £15 15s. This course will be conducted by the honorary staffs of the Royal Infirmary and various special hospitals, and graduates will be attached in groups of four to the charges of the honorary physicians for individual practical and clinical work. In addition to these courses special instruction in individual subjects, such as diseases of the blood and of the nervous system, urology, anaesthesia, neurological surgery, etc., may be taken by graduates specially interested. Graduates may obtain the syllabus from the secretary of postgraduate courses in medicine, University New Buildings, Edinburgh.

On the occasion of the eleventh congress of the German Society for Investigation of the Circulation recently held at Bad Nauheim, Professor Hess of Zurich was awarded the Carl Ludwig medal and Professors Spalteholz of Zurich, Jaksch of Prague, Geheimrat Aschoff of Freiburg and Professor Hering of Kiel were nominated honorary members of the Society.

### Classification of Adventitious Sounds

SIR—Examiners in medicine realize the confusion in the minds of candidates caused by the different terminologies used by their teachers. It would be a great help if we could all use the same terms. Could we not agree for instance to abandon the misleading terms 'dry' and 'moist' when applied to rales and substitute 'rhonchi' and 'rales' respectively? 'Rhonchi' would then be described as sonorous or sibilant according to whether they were produced in larger or smaller tubes. 'Rales' would be divided into bubbling (non consonating non-crepitant) and crackling rales (consonating crepitant) and each variety would be subdivided into coarse medium and fine. Could we not further agree strictly to confine the term 'crepitation' to the finest of all rales the hair-like crackling sounds heard in early pneumonia collapse and oedema which signify that the parenchyma of the lung is involved? Too often this term—or more briefly 'creps'—is used indiscriminately for any kind of rales. This classification appears to be the one most used and it is given in several standard textbooks. It is simple and each sound corresponds to a definite physical condition of the lung.

Candidates are also confused about the varieties of breath sounds. The finer distinctions can be left to the experts, but it seems to me that students should at least be expected to recognize vesicular breathing, vesicular breathing with prolonged expiration, broncho-vesicular breathing and the two varieties of bronchial breathing—tubular and cavernous. A simple explanation of the physical laws governing the production of sounds by fluid passing through tubes of varying calibre followed by a description of the methods by which each of the various structural alterations such as consolidation, emphysema, asthma, oedema, cavitation, etc. modifies the sounds would enable students to make correct deductions from physical signs and visualize the anatomical basis for the sounds. Many candidates do not see any contradiction in stating that they have found vesicular breathing with crackling rales, bronchial breathing over an emphysematous lung or whispering pectoriloquy with normal breath sounds. The modern student of medicine has a sufficiently difficult task without making it more difficult by the present confusion over physical signs.—I am etc.

Birmingham April 18

W H WYNN

### Origin of Cancer

SIR—The contribution of Dr W Cramer on the origin of cancer in the *Journal* of April 16 (p 829) was of absorbing interest and puts the problem before us in the clearest possible manner. What is now needed is an explanation of the sudden change which occurs in a cell or a small group of cells in a pre-cancerous area endowing it with the power of continuous growth. I have long been impressed with the analogy between this sudden change in the rate of growth and behaviour of cells and that equally sudden change which occurs in a colony of protozoa when conjugation takes place between two cells. The reproduction of the members of the colony by cell division has been slowing down, obvious signs of senescence and degeneration have appeared, the death of the whole colony is threatened and then the

whole picture is altered by the conjugation of two of these senescent cells and a new race of young and vigorous cells arises with a vastly enhanced rate of reproduction.

The only instance of conjugation in normal human or animal physiology is that between spermatozoa and ovum and it endows the resulting zygote with sufficient reproductive impetus to carry on cell-division at a gradually reducing speed until the final exhaustion and death of the organism. But conjugation occurs among the cells of malignant growths and was described by Basnford who observed it as identical with the process of conjugation seen in many protozoa. The cells of malignant growths therefore in this respect at least have reverted under the stress of long continued irritation to an ancestral type and have resumed the habit of reproductive alternation between fission and conjugation. Is not the sudden change on which Dr Cramer lays stress the moment of the first conjugation? Conjugation alone is sufficient to explain the peculiar powers of growth and infiltration of cancer cells and explains also their apparent immortality through transplant after transplant. Reversion or highly specialized zoological types to primitive prototypes under adverse environmental conditions is of course well known. The development of cancer in a tissue which has been long under stress is from this point of view a triumph of the cell against the threat of extermination.—I am etc.

Ashton-under-Lyne April 19

J V FIDDLA

SIR—It is to be regretted that in his otherwise very convincing article on the origin of cancer (*Journal* April 16 p 829) Dr W Cramer should make one statement that surely must be challenged on purely statistical grounds. He would seem to conclude (pp 83-4) from the fact that 99 out of 155 women (65 per cent) with cancer of the buccal cavity and oesophagus have a coincident simple achlorhydric anaemia that this is an abnormally high rate. It may be or it may not be. For he gives no evidence that among 155 women with say grey hair an even higher proportion than 65 per cent may not have a similar anaemia. However Dr Cramer then goes on to a quite (presumably) from the facts he has quoted that in two-thirds of the patients suffering from this type of anaemia one may expect the subsequent development of cancer in certain sites—that is buccal cavity and oesophagus—if treated not treated for their anaemia. Surely not? Not even if all the patients with that type of cancer suffer from this form of anaemia must two-thirds of these with the anaemia necessarily suffer from that type of cancer. What is the proportion of women over the age of 40 years who suffer from simple achlorhydric anaemia?—I am etc.

London SW 19 April 22

G I WATSON

### Prevention of Cancer

SIR—The important papers by Dr W E G (March 12 p 331) and Dr W Cramer (April 16 p 829) and the leading article of April 16 (p 855) provide constructive guidance to the cancer problem as it arises. Observe the stress laid by Dr Cramer on the prevention of realizing that cancer is a preventable disease. The recognition of cancer as a preventable disease is in my opinion one of the most important steps in scientific cancer research. He bases his argument on the observed fact that most cases of cancer are preventable but is always preceded by a long period of incubation occupying a considerable fraction of the span of the life of the species, during which the tissue in which the

phenomena of malignancy eventually develop undergoes definite pathological changes 'In certain tissues,' Dr Cramer continues, 'such as the skin the tongue, and the vulva—tissues readily accessible to inspection—the existence of pre cancerous conditions has long been recognized by clinicians, although pathologists have not always agreed that these are special examples of a general phenomenon applicable to the vast bulk of the cases of cancer occurring in all organs'

The growing acceptance of the creed that cancer does not attack a healthy organ or tissue is encouraging, once this is accepted, the prevention of cancer becomes practical politics. In regard to surface cancers—of the skin, lips, tongue, etc.—prevention is agreed to be a matter of avoiding habitual irritation by pipe-stems, jagged or septic teeth, hot drinks, etc., it is not a long leap to the conclusion, as Dr Cramer points out, that internal cancers could be prevented by similar or corresponding means. In my presidential address to the Hunterian Society on stasis and the prevention of cancer (*British Medical Journal* December 25, 1920, and Chapter XX of my book, *Chronic Intestinal Stasis*) I discussed this matter and showed, conclusively as I thought, that cancer in every situation occurred only after long periods of chronic disease of the affected organ or tissue. Proof that cancer is not inevitable is afforded by the well-known observations of Sir Robert McCarrison among the people of Hunza (see, for instance, his article in the *Practitioner* January, 1925). He writes

Gastro intestinal complaints—dyspepsias, gastric and duodenal ulcers colitis, and appendicitis—are as uncommon amongst them as they are common elsewhere. Even cancer is so rare that in nine years practice I never came across a case of it. There can be no doubt that their freedom from disease is largely due to the food they eat and the health-giving life they lead in a bracing climate.

A statement often repeated is that "a million people can't be wrong", this is grotesquely untrue. Not a mere million, but a thousand million people can be, and are, wrong as regards diet. If anyone doubts this, let him mark the complete confirmation afforded by Denmark during the war, this was no less than a large-scale demonstration of the effects of strict dieting on the health of a nation.

Shortage of food was so severe that strict rationing was necessary: this was entrusted to Professor Hindhede who was given dictatorial powers. Briefly he placed Denmark on a diet consisting of coarse whole rye and whole-wheat bread containing a large amount of bran, with small rations of skimmed milk butter margarine potatoes, and a very small amount of meat (Spirits, tea, and coffee were practically unobtainable). On this Spartan diet remarkable results were obtained: the death rate for the whole country fell to the lowest level ever seen in any civilized country—namely, 10.4 per thousand. Then came the epidemic of Spanish influenza that devastated Europe. Denmark did not escape but the death rate from influenza was far lower in Denmark than in any other European country. After the war when rationing was no longer enforced the Danes gave up the healthy diet imposed by the war, with the result that the death rate soon rose to pre war figures.

The way to the prevention of cancer is perfectly simple and obvious in itself, but is made extremely difficult because it entails an entire revolution in the habits, especially the feeding habits of the civilized world. It should be possible for those in authority to ensure a healthy natural diet for the entire nation but it would entail very severe discipline on the part of the people and a dictatorship with unlimited authority to control or suppress undesirable products. Mussolini in one of his first edicts

banned white bread and directed that the nation's bread be made from a mixture of whole-meal grains. A similar edict would have to go forth in this country, but equally important and far more difficult would be the drastic curbing, if not the entire prohibition, of those vast industries that fill shop windows and restaurant counters with unwholesome dainties—for example, those made from concentrated sugar, especially sweets, chocolates, and sugary cakes and pastries. The extensive advertising of foods and drinks that can be shown to injure the organs and tissues, especially the digestive organs, would not be allowed, concurrently, every measure would be adopted to persuade the people that the craving for sweetmeats and chocolates is a pernicious one, that it should be conquered, and the palate should be re-trained to enjoy the delicate flavours of natural ripe fruits.

The human race would be healthy on the natural diet for which it was evolved, a return to it may seem Utopian, yet it will have to be faced, and the sooner the better. The firms that unload unwholesome products on the public must transfer their activities to more health giving ends. I am convinced that the result would be an amazing improvement in the nation's health and would reduce the incidence of cancer to a sporadic case here and there, and not, as some seem to expect, merely transfer its incidence from one organ to another. The Government's scheme for ensuring national fitness will do no more than touch the fringe of the matter if it does not include a very strict supervision of the nation's diet, so as to bring it back to the natural one for which the digestive organs are intended—I am, etc.,

London, W 1, April 18

ALFRED C JORDAN

### Carcinoma of the Palate

SIR—Dr John R Nuttall's paper in the *Journal* of April 16 (p 839), drawing attention to the relation between neoplastic lesions of the palate and those of the maxillary antrum, will do much to effect earlier treatment of these cases. When the antrum is not completely filled by new growth my method (*Journal* July 10, 1926, p 38) of injecting lipiodol into the antrum before x-ray examination usually outlines the neoplasm successfully. Neoplasms of the antrum at times are missed by the rhinologist because he has drained an antrum, which he has presumed to be simply the seat of sepsis, by the intranasal method. The Caldwell-Luc or Denker procedures would have prevented this failure—I am, etc.,

Manchester April 17

W BRYCE MCKELVIE

SIR—Dr John R Nuttall in his article in the *Journal* of April 16 (p 839) draws attention to the fact that in quite a large proportion of patients suffering from carcinoma of the roof of the mouth the disease has already involved the antrum, indeed the buccal lesion may be merely an extension of an antral growth. All the cases referred to have evidently been treated by irradiation. Before treatment investigations were carried out in order to ascertain whether or not the antrum was involved some reliance was evidently placed on what is called the needle test. This can be of no value in estimating the extent of the antral involvement, and, moreover, it might lead to dissemination of the disease. During a surgical operation it is always possible to discover the extent to which the disease has invaded the antral walls, but obviously it is generally impossible to say whether it originated in the mucous membrane of the antrum or in that of the alveolus. By a technique in which surgical and electrocoagulation are combined, all tumours which

are reasonably localized and some which are rather extensive, can be dealt with the risk to the patient being practically negligible. In my opinion surgery without irradiation is much more likely to lead to permanent freedom from the disease than is irradiation without surgery, although in some cases the two methods may be combined with great advantage to the patient.

One of the merits of a surgical procedure is the large opening which results from removal of generally the greater part of the roof of the mouth on the affected side. Through the resulting opening the walls of the operation cavity can be periodically inspected and if a recurrence takes place its position can be located with some certainty and suitable treatment adopted. The opening much facilitates should such treatment be thought desirable the local application of radium. Even in cases where the disease does not appear to have affected the hard palate a portion of the roof of the mouth should be removed if only to render thorough after inspection of the region more easy. The defect in the palate can easily be filled up by a suitable dental appliance. The published records of treatment by irradiation do not encourage me to abandon surgical measures which I have employed for the last twenty five years and which owing to improved technique are giving much better results than were formerly obtainable—I am, etc

NORMAN PATTERSON

### After-effects of Modern Treatment of Carcinoma

SIR—Mr Percy Furnivall's account of his treatment by radium and x rays and the after-effects (*Journal* February 26 p 450) has brought forth a goodly correspondence in your columns. He has done a service in stating his experience, and all interested will wish him a speedy and complete recovery.

In this letter I am concerned not with the dosage of radium and x rays but with the medical treatment of the patient. Apart from the treatment of pain it any and general considerations for the patient's comfort I have found that a great deal can be done towards well being and recovery by a careful watch on the blood condition and the administration where anaemia exists in however small degree of liver extract with perhaps iron in an easily assimilable form. My attention was first drawn to this subject by an account in the *Journal* about four years ago in which Dr J H Douglas Webster described the successful treatment of x ray sickness by intramuscular injections of liver extract. Also there appeared about the same time in the *Epitome of Current Medical Literature* a description of similar good results from a Continental source. But besides this primary form of irradiation sickness which usually passes off in a day or two there is the delayed type in which real ill health persists more or less for a considerable period of time.

The formed elements of the blood are all affected by radiations the erythropoietic tissues less than the leucopoietic but the red cells and haemoglobin may be severely affected where some degree of anaemia is present previous to radium and x ray therapy.

In the patient suffering from carcinoma and in a debilitated state of health probably following operation and loss of blood an anaemia already exists. Hence the necessity for a blood count and the administration of liver extract and iron before radiation it required and certainly during treatment and for some time afterwards. During the last few years I have given these patients according to their degree of anaemia and debility capsules

containing liver extract with a trace of iron and vitamin B much to their benefit. Contraindication to this treatment may be found in a very few cases—I am etc

Hove April 16

J M ANDERSON M.D.

SIR—Mr Musgrave Woodman's letter (*Journal* April 16 p 871) proposing team work shows a way in which radiotherapy may be carried out efficiently and workers may assist materially in avoiding the disastrous after-effects which have been described in the recent correspondence. The most distressing after-effects would appear to have arisen when radium has been given in conjunction with x ray therapy and therefore the radiologist should be included in the team in order to ensure co-operation between the radium and x ray therapists.

At the regional radium centre at the Royal Hospital Wolverhampton team work in radiotherapeutics has been the rule during the past eight years. Radium therapy is controlled by a radium committee which from its beginnings now consists of all members of the staff who use radium including the pathologist and radiologist. This committee meets weekly and all new patients to whom radium treatment is proposed are examined and after consultation the patient is treated by the member of the staff introducing the case. All old cases attend these meetings for examination and follow up study. No patient receives radium treatment unless he or she has been brought before the radium committee except in cases of emergency such cases being reported at the next meeting. Radium therapists may object to loss of independence by this procedure but in this hospital no objections have been raised and the conditions have been willingly and loyally observed. It is considered that facilities for consultation and the opportunity of seeing a number of cases throughout the course of their treatment by different methods more than compensate for any loss of individuality. Throughout the course of his disease the patient is treated by a team and the dangers of complications from irradiation are minimized especially in those cases in which the application of radium is followed by deep x-ray therapy—I am etc

### Control of Sulphanilamide Treatment

SIR—Under the above heading Dr W J Honmann (*Journal* April 23 p 923) suggests that white cell counts in patients under treatment with sulphanilamide might all be undertaken as a routine so that some indication may be given of possible toxic effects before rather than after the event. The suggestion that such counts would give the desired warning has been made before in regard to this and other drugs but in reporting a fatal case (*Journal* July 17 1937 p 105) I drew attention to the fact that serial leucocyte counts had given no warning of impending agranulocytosis. Similar observations appear to have been made in other fatal cases. Test doses of an antidote in some recovered cases apparently due to the leucocytes have however shown granulopenic reactions. No effect of the procedure may be useful in some instances. No effect of the amount of labour involved in carrying out serial leucocyte counts in all patients receiving drugs producing agranulocytosis usually renders such a proceeding impracticable. Davis and Frisell (*J Lab Clin Med* 1937 23 107) reported observations on the leucocytes in a series of thirty-two cases treated with amiodip and in none did they observe any important effects. This interesting suggestion

might be due to the fact that treatment was always stopped on the occurrence of any symptoms of toxicity such as indigestion, lack of appetite, or dizziness. The value of such a method is doubtful, but it would at least be more practicable than routine leucocyte counts—I am, etc,

Royal Infirmary, Bradford, April 24

C J YOUNG

### First Mention of Sulphonamide

SIR—Recent correspondence in your columns prompts me to call attention to what I think has been overlooked by workers on the chemotherapy of sulphonamides. I refer to a suggestion made as long ago as 1919 by Heidelberger and Jacobs, who published a series of papers on "Syntheses in the Cinchona Series," of which the third was called "Azo Dyes derived from Hydrocupreine and Hydrocupreidine" (*J Amer chem Soc* 41, 2131). In this paper they describe the preparation of the meta- and the para-phenylazo-derivatives of hydrocupreine, and refer in passing to the preparation of *m*- and *p*-aminobenzene-sulphonamides, both of them substances already known. The point of historical interest is that these authors wrote (p 2132) "Many of the substances described in this paper were highly bactericidal *in vitro* a property which will be discussed in the appropriate place by our colleague, Dr Martha Wollstein."

A search of the literature between 1919 and the present day having failed to reveal any publication by Dr Wollstein, I communicated with Professor Heidelberger last summer on the matter. He was good enough to explain that they had been unlucky in their choice of substances to investigate, for "the bactericidal power of the sulphonamido-azo-hydrocupreines was not as high as some of the other substituted dyes, nor were the animal experiments encouraging." Professor Heidelberger added that he could not recall whether any therapeutic tests were ever carried out with this dye. Dr Wollstein's work was brought to an end, and no account of it was ever published. It is true that no reference is made, in the words of Heidelberger and Jacobs quoted above, specifically to the simple sulphonamides, or to their azo-compounds with alkaloids, and it would probably not be claimed by these authors that they had actually forecast the bactericidal properties of the sulphonamides. Nevertheless, the passage quoted does suggest the possibility of further chemotherapeutic studies and one cannot help wondering whether some of the subsequent work may not have been inspired by this paper, which was published from the Rockefeller Institute. The inspiration must, in that event, have been subconscious for it has not been possible to find in the publications of German investigators any reference to the work of Heidelberger and Jacobs. Professor Heidelberger himself believes that some reference was made in one of the earlier papers by the French workers, but I have not been able to trace this—I am, etc,

A L BACHARACH MA, FIC

Greenford Middlesex April 21

### Is it Influenza?

SIR—Is it possible that influenza can at times show atypical attacks which breed true to type in the form of an epidemic or must the symptoms always be classical for the diagnosis of influenza to be made? We are often told for instance to beware of labelling cases of early tuberculosis as influenza but what is one to call such a collection as the following?

There has been here this last winter an epidemic of catarrh of the upper air passages characterized by in-

sidious onset and great resistance to the usual forms of treatment, and even to well-tryed palliatives. Tracheitis has been the most outstanding feature, but there has often occurred as well a pharyngitis involving the soft palate but leaving the tonsils almost unaffected. The typical appearance was as if a streak of red paint had been placed upon each anterior pillar, and the accompanying subjective feeling was of a most annoying tightness in the throat, without actual difficulty in swallowing. The nasopharynx and even the middle ear have also been involved fairly often. These symptoms, besides being insidious in onset were liable to fluctuations from day to day, so that it was difficult to say when a patient had really recovered. There was no prostration, and yet many people found it impossible to continue their work while the disease was at its worst. Many showed no rise in temperature.

The symptoms do not sound very striking on paper but it has been obvious that all the cases belonged to a definite disease entity. It has usually been dubbed "influenza" on certificates, but when compared with the epidemic of the preceding winter it seems to have been misnamed. As was seen in the first epidemic, and in sporadic cases, influenza strikes with dramatic suddenness, but victims of this epidemic have succumbed slowly and protestingly, and they have not been prostrated rather have they been annoyed at the disconcerting disability produced by seemingly trivial symptoms. The intractability of the cough, etc, have been mentioned as features of influenza, and in this respect the disease can lay claim to the name. But the usual depression of convalescence has been lacking, and this is always emphasized in true influenza. I have not made a count of the total number of cases I have seen, but I am convinced they have been as many as the typical influenzal ones the year before, so that the term "epidemic" is permissible, I think. And it will be obvious that enough cases have been seen for one to feel certain of the facts.

I believe that there has been here a new infectious disease of the upper air passages, if not, then the usual descriptions of influenza must be revised to include such epidemics as this—I am, etc,

Redruth, Cornwall, April 22

L A RIDDELL

### Influenza, a Misused Term?

SIR—Claiming that the causative organism of influenza has at last been discovered and that the study of the symptoms of 120 patients, chiefly in the hospitals of the defence services, has established its symptomatology, the Medical Research Council in its annual report seeks to criticize the popular use of the term "influenza."

There is a heterogeneous mass of ailments in general practice which go by the name of minor maladies. It is the periodic exacerbation of certain of these maladies which has been called epidemics of influenza. Save for the numbers affected there is nothing unusual about the ailments of these periods; what relation, therefore, if any, have these exacerbations to the illness described in the annual report as the "real epidemic influenza?"

Following the pandemic of 1918-19 a report was issued by the Ministry of Health. It contains a description of the symptoms of that pandemic, and the writer stated that he was not prepared to call it "influenza." It is worth studying again, for the summer and winter epidemics according to the writer, "presented very different clinical features. Which of those was the real epidemic? Certainly the graver winter epidemic looks more like that condition which in the MRC annual report is described as 'febrile catarrh,' and one should note that among

the symptoms of the Council's real epidemic influenza there is now no mention of the dreaded blueness of that period

I possess a day-to-day record of the symptoms of new patients as they presented themselves during the 1922 epidemic and there is an obvious variation in the symptomatology of the epidemic as between its initial and terminal stages. As the patients affected presented no fixed symptomatology that epidemic must fall from grace. I cannot write of the next three epidemics in any definite detail but during those periods it became more apparent than ever that the well-tended healthy type or individual was the readiest sufferer. Sir William Hamers observations in regard to types led to the analysis of the 1922 epidemic which is used above and the sequence of the clinical signs revealed in that analysis induced me to study the 1936 epidemic from a new view point. There was the same variation in symptomatology but it was evident that this variation was related to a different type of individual affected at different stages of the epidemic. Therefore the 1936 epidemic fails also to have been a real epidemic of influenza. Isolated cases of illness described in the report I have often seen but never enough at any one period to deserve the name of epidemic. Furthermore, it can be demonstrated in any epidemic that if the minor malady is properly handled when it appears in a household deaths and complications are negligible.

If the symptomatology of segregated individuals is different from the symptomatology of individuals in ordinary life during similar periods then it raises many interesting conjectures. Some of these can have a bearing on the bacteriology of the condition. I am not interested in influenza from this standpoint because I still fail to see that it can have any practical value (can we vaccinate a population?) but as the accusation of misuse of the term comes from this angle I would like to draw attention to a discrepancy in the report.

If reference be made to the articles in the *Journal* of September 11 1937 (pp 513-516) by Drs C. H. Andrews and C. H. Stuart Harris—and it is on their work that the Medical Research Council relies to a great extent for its information—it will be noticed with regard to the so-called febrile catarrhs that the statement "influenzal virus was not recovered" is converted into "influenzal virus is not concerned." There still remains a possibility therefore that influenza may be found after all to cover many different manifestations. It is not from any desire to criticize any research work nor to trouble the Council with my own but the Council can have little idea of how such premature assertions can affect panel doctors. The report will come before the Ministry and another formula will be devised to tighten the certification of incapacity, and unless the panel doctor is prepared to face an inquisition the term "influenza" must go. In spite of that there is a connecting thread running through the whole problem of minor maladies whether it be concealed under a conglomeration of names or indicated by one—I am, etc.

### Calcium and Phosphorus Deficiencies

SIR,—In the paper by W. E. Gaunt, J. T. Irving and W. Thomson in the *Journal* of April 9 (p. 770) the statement is made that numerous experiments with large animals have demonstrated that calcium and phosphorus lack is a common cause of deficiency disease retardation of growth and low viability in young at birth. As the main authority for this statement the papers of Elliot Crichton and Orr (1922) and Elliot and Crichton (1926)

are cited. In the former paper it is alleged that rickets is due to a lack of calcium in the diet and that the disease can be prevented or cured by raising the proportion of calcium in the ration to that of the phosphorus. During the years 1922-6 I had the opportunity of closely observing in the piggery attached to the Rowett Institute (which had an annual population of hundreds of susceptible pigs) the effect of this balancing of the ration of the calcium to that of the phosphorus. Rickets as a natural disease occurs most often in January and February (owing to the lack of sunlight) and in the stock just alluded to fed on this balanced ration during January and February of these years hardly a pig which could be the subject of the disease escaped it.

The second paper cited has reference to the effect on young sheep of adding calcium to a ration deficient in this substance. I refrain from discussing the merits of this contribution but I have in my possession complete protocols (which were and are available to all workers in the Institute) of too much more elaborate and detailed experiments of the same type carried out at a later date in the Rowett Institute under essentially the same supervision. The first of these experiments is designated in the official record as "sheep experiment No. 8" and was conducted during the autumn, winter and spring of the year 1928-9. It is recorded that the group on the basal ration with calcium "adjusted" by the addition of calcium carbonate showed marked bent leg stiffness, going off legs, walking with difficulty, loss of weight and loss of health. As evidence of the two latter conditions one notes that at a time when in other groups as many as six animals were being sold at prices ranging from 36s. 9d. to 47s. 3d. each only two out of this group were saleable and for these 26s. 9d. per head was obtained.

The second experiment is termed officially "Garrochoran sheep at Rowett Institute experiment 1" and was carried out during the autumn, winter and spring of the year 1931-2. In this case group 3 in which the basal ration was balanced with calcium carbonate showed stiffness and bent leg while the weights of the animals and the calcium in the blood (ranging from 0.63 to 0.75 mg. per 100 ml. from March 10 to March 17 1932) were of the same order as those in the sheep fed on the basal ration.

It seems to be the opinion of Gaunt and his co-workers that the addition of calcium salts (their views on the additions of phosphorus salts are not quite clear) to the "survey diet" (human) greatly improves this diet as tested on rats. Unless rats have a metabolism differing from that of the other animals experimented on this result is completely out of harmony with those obtained in the pigs above referred to in the pigs discussed in my paper in the *Journal* (1933 2 399) in the sheep of experiments 8 and 1 and in chickens (McGowan and Emslie *Biochem. J.* 1934 28 1.03). The crucial factor in these cases is of course vitamin D which is not mentioned in the paper under discussion—I am, etc.

Aberdeen April 21

### Abuse of Ephedrine

SIR,—As a fairly frequent sufferer from common colds it was with some interest that I read Dr. R. R. Fergus's letter on the abuse of ephedrine (*Journal* April 16 p. 874). My rhinorrhoea ordinarily lasts a fortnight and has exceeded this time on one occasion only. This was when I made use of an oily preparation containing ephedrine and the rhinorrhoea persisted for over a month, my nasal mucosa remaining congested during this time.

and the airway becoming intermittently blocked I am therefore of a mind with Dr Foote when he suggests that such preparations may damage the nasal mucosa. I do not agree, however, that inflammation of the antra is the usual end-result. On the contrary, I think that the occurrence of pain in the sinuses—frontal, maxillary, or ethmoidal as the case may be—is the main indication for the use of oily preparations containing ephedrine. As there is a risk of damaging the mucosa in some individuals, I give the preparation once or twice daily only in these cases according to the result. I also instruct the patient, when he has finished instilling the drops, to adopt for a short time such an attitude as may be consistent with the drainage of the sinus which gives rise to the discomfort. I have used this treatment with success in some cases where a family history of antral trouble was given. The extent to which the mucosa of the sinuses inflames during the average common cold is not accurately known, for the disease is not lethal. It seems to me unlikely that the intranasal instillation of vasoconstrictors leads to their introduction into the sinuses in such quantity as may directly affect the mucosa one way or the other. On the other hand, the shrinkage of the membrane in the neighbourhood of the ostia is probably beneficial, promoting free drainage if the application has been made successfully—I am, etc.,

Grangemouth April 19

J M HENDERSON

SIR,—In your issue of April 16 Dr R. R. Foote suggests that his experiences may call forth some confirmatory evidence. May I hope that you may find space for the following?

The artificial production of vasoconstriction and the drying-up of the secretions is contrary to nature. The moisture secreted by the mucous lining of the walls of the nose is essential for the normal hygiene of the respiratory passages. The sudden increase caused by irritating particles or by the common cold must be recognized as a cleansing flow to be encouraged and followed by the clearing blow. In no case can it be safely inhibited. Repeated attempts to desiccate the surface will result in a sort of tanning process, with loss of sensitivity so that the call to clear is not recognized even if it comes. Then again, the vitality of the cilia is diminished or lost for they cannot survive on a dry surface. Oily emulsions, too, impede their action. The temporary relief that comes from the widening of the airway as the mucous membrane shrinks is so welcomed by the victim that he almost naturally tends to make it permanent. When that has been accomplished the foreign matter accumulates. The germs cease to be disturbed and routed out so that they flourish and multiply in the incubator-like cavities. The toxic products are scattered as they form infecting the neighbouring structures or the blood stream.

The germicidal properties of the nasal, as of the lacrimal fluids are of the utmost importance for the general welfare—I am, etc.,

OCTAVIA LEWIN, M B, B S Lond

### Auricular Fibrillation in Cardiazol Treatment of Schizophrenia

SIR—The following case appears worthy of note

The patient an intelligent man of 33 formerly an engineer, had been suffering from catatonic stupor since 1931. He was resistive negativistic mute and destructive. His habits were degraded and he was incontinent of urine and faeces and coprophagic. It was decided to include him in a series of cases suitable for cardiazol convulsant therapy. A physical examination showed no abnormality and there was nothing significant in the history. Preliminary investigations of the

blood bromide, blood urea and urine were carried out according to routine. These were all found to be normal. The blood pressure was 120/85 mm Hg. On March 23, 1938 at 11.30 a.m., he was given an intravenous injection of 5 ccm. of a 10 per cent solution of cardiazol into the right antecubital fossa. A major convulsion followed immediately with tonic and clonic phases. The patient appeared rather paler than usual and frothed a good deal through his nose. His pulse had become irregular in rate and volume, and showed the characteristic features of auricular fibrillation, the rate was about 90. The heart was not enlarged. Injections of digitalin and strychnine were given, followed by tr. digitalis by mouth. The heart continued to fibrillate for twenty-four hours the rate varying between 64 and 118, but was usually between 70 and 90. The digitalis mixture was discontinued and the pulse remained regular and has been so ever since.

On March 26 he passed some blood and mucus per rectum with a great number of threadworms, no more have been passed since then. A blood count revealed no abnormality. The red cell count was 5,350,000, haemoglobin 100 per cent, colour index 0.93, the leucocyte count was 7,800 and there was no eosinophilia, the diameter of the red cells was  $7.3 \mu$ . His weight has varied from 11 st to 7 st. At present it is 9 st 8 lb. It was not considered advisable in the circumstances to continue with the cardiazol injections—I am, etc.,

Cefn Coed Hospital, Swansea, April 11

S H LUBNER

### Chronic Littritis

SIR,—Might I finally sum up my views as to the mechanics of hand syringing applied to the urethra? In the experiment reported by Dr Sydney M. Laird (*Journal* April 9 p. 816) the pressure recorded by the manometer is in the case of the douche a close approximation to that applied to the urethra, but in the case of the syringe, by reason of Bramah's principle, the level of the manometer will depend on the relation between the cross section of the syringe and that of the tube, as well as on the force exerted on the piston. Dr Laird applied a ligature to represent the contracted sphincter of the urethra. Under natural conditions the anterior urethra when this sphincter is contracted forms with the syringe a closed system, without the relief afforded by the side tube in the experiment. When the system is filled with fluid—which is of course incompressible—the force tending to drive fluid into the glands of Littre is  $NP + E$  lb per square inch (where  $P$  is the pressure applied to the piston, and  $E$  the elastic recoil of the peri-urethral tissues both measured in lb per square inch), in the case of the douche at a height of 3 ft this force cannot exceed 12 (hydrostatic pressure) +  $E$  lb per square inch. Since a pressure of more than 12 lb per square inch can easily be exerted on the piston it is clear that more force can be applied with a syringe than with a douche. It seems to be true that with a relaxed sphincter the pressure produced by a syringe will be even lower than that produced by a douche, but it is easy to see that in either case the pressure will be low by reason of the comparatively free flow into the bladder.

In actual practice the properly instructed patient relaxes the sphincter when using a douche, and even if he fails to do so the resultant pressure is low and has a maximum value fixed by the height of the douche. The syringe is commonly used by the ignorant who do not know how to relax the sphincter, nor the importance of doing so, it is also probably easier to acquire the art of relaxing the sphincter when it is subjected to continuous but low pressure than when brief but forcible pressure is applied. I submit, therefore, that the contention that the hand syringe can produce excessive intra-urethral pressure

is maintained but I must also apologize for certain obvious fallacies in the reasoning which I previously advanced in support of this conclusion—I am etc

Salford April 25

R C WEBSTER

SIR—This correspondence on the aetiology of chronic litritis between Dr R C Webster and myself has already encroached considerably on the space in the *Journal* and therefore, I cannot comment on Dr Webster's remarks concerning ear maintenance ear syringing and infiltration anaesthesia (*Journal* April 23 p 921). All are irrelevant to the discussion as it is manifest that the irrigation obtained by the patient using a hand syringe is not comparable with that possible when an independent operator is conducting the manoeuvre. In conclusion may I express the hope that this correspondence far from detracting from the very real value of the major part of Dr Webster's original paper (*Journal* February 26 p 448) has actually focused increased attention upon it—I am etc,

Liverpool April 23

SYDNEY M LAIRD

### Pasteurization of Milk

SIR—I have received several letters suggesting that my part in the milk controversy is animated by a financial interest in a certain milk supply company. As that may influence some of those interested I wish at once to say that I have not one penny invested in any such company and never had much to my regret. I have no axe to grind. Like Dr C O Hawthorne (*Journal* April 23 p 917) I do not think that the theory that pasteurization of milk has any appreciable influence on fertility is of any importance when weighed against the necessity for a clean and germ free milk supply. The buck and doe test cuts no ice; this can be said of most tests. A healthy nation even supposing it should be slightly less fertile is far and away a sounder proposition than a large nation whose stamina is undermined by a contaminated milk supply. The fall in the birth rate is not, as we know well, dependent on diet but on those preaching a gospel of birth control—whether rightly or wrongly does not enter into this discussion.

Neither Certified Grade A nor Grade A T T milk is safe as they all contain living active bacteria. Cows tested for tuberculosis to day may be negative but the same cows tested in three months may be positive. During that interval milk from these cows has been supplied to the public. Therefore there is no definite guarantee that milk from a T T herd is free from tubercle bacilli unless and until it has been pasteurized.

I give place to no one in my desire that milk producers and farmers should have all the encouragement and help that it is possible to give them, but that does not override a greater desire to see being built up a healthier and sounder nation than we have to day. Of course an ideal milk is a raw milk, provided such can be produced that is clean pure and uncontaminated. To this day such a milk has never been procurable.

To the question put to me in the letter by Lord Rowallan (April 23 p 918) regarding the pathogenicity of *Bact coli* it must be quite evident from my letter that I regard all *Bact coli* as pathogenic. I regret that I do not quite grasp what is the meaning of the request for experiments to decide the relative growth in raw and pasteurized milk of pathogenic germs which have passed successfully through the process. What process is referred to? If pasteurization is meant no pathogenic germs

have successfully passed through the process. Any such found in pasteurized milk subsequently to pasteurization have been introduced after the cap has been interfered with. Pasteurization does not prevent subsequent contamination if the milk is improperly handled or stored.

The question of a national milk supply resolves itself into this: What class of milk is likely to be most beneficial to the general health and stamina of the nation? Is to be raw milk containing living active pathogenic bacteria even if the fertility and vitamin ratios are unimpaired or pasteurized milk which is clean and germ free but which may be slightly deficient in its vitamin and fertility balance? The answer is self evident—I am etc

London SW 16 April 23

JAMES KIRKLAND

### Distress in China An Appeal

SIR—It is difficult if not impossible for people in this country to realize the extent and severity of the destitution and physical suffering of many thousands of the Chinese resulting from the present hostilities. Recent events in Europe together with the remoteness of China have also distracted attention from the catastrophe in the Far East. During the last five months we have received the most urgent appeals for help and have brought them to the attention of the excellent organizations that are doing everything possible to mitigate the distress in the provinces of China where suffering is greatest. The answer has invariably been the same. Every penny that comes in is pledged in advance to support the relief schemes already in operation—we cannot consider any new commitments.

A letter dated February 7 1938 coming from Dr C Y Wu Director of the Chinese Red Cross, Hong Kong Bureau contains the following passage:

We are still urgently in need of the more valuable supplies such as surgical instruments sera adrenaline calomel coramine ferrous carbonate 0.3 gramme ferri et ammon citrati rubber gloves Thomas splints oil cloth gauze and gauze bandages 6 inches by 3 yards autoclaves anaesthetic machines and burners instrument sterilizers rubber tourniquets and tubercle Funds are also urgently needed to finance our field units. Each unit consists of five surgeons and fifteen nurses and orderlies. We now have thirty-nine such units operating at the various fronts and it requires a tremendous cost of medical and surgical equipment—700 dollars to support one unit for six months. I hope you can assist in this matter.

It seems to us that this appeal should be addressed direct to the profession in this country. Here is one of the specific where a small gift in money or in kind will surely be turned to account. Some may feel that whatever is collected will be no more than a drop of relief in a vast ocean of suffering. This is not the view of those who are caring for the victims of war and famine in China.

The signatories of this letter are prepared to take personal responsibility for receiving and transmitting all gifts from the medical profession to Dr Wu in Hong Kong and it is our earnest hope that you will have a good deal of work to do. The address for reception of gifts of all kinds is the China Institute 91 Gower Street London WCI—We are etc

## Obituary

### SURGEON VICE-ADMIRAL SIR ROBERT HILL, KCB KCMG FRCS

Surgeon Vice Admiral Sir Robert Hill, R N (ret), who died at Henley-on-Thames on April 18, was Principal Medical Officer of the Grand Fleet during the last two years of the war, and Director-General of the Medical Department of the Admiralty from 1919 to 1923, in which year he retired from the Service.

Born on July 25, 1865, the son of Dr Samuel Hill,

he was educated at the Middlesex Hospital, and took the MRCS, LRCP and LSA in 1888. He was elected FRCS Eng in 1923, and also received the honorary FRCS Ed. Entering the Navy after qualifying, in a varied and interesting career he served in the *Ophir* during the Royal colonial tour of 1901, in HMS *Renown* when King George V and Queen Mary, then Prince and Princess of Wales, visited India in 1906, again in 1911-12 he was with Their Majesties in the *Medina* on the occasion of their voyage to India for the Durbar. During the war he served in the North Sea, and from 1916 to 1919 was Principal Medical Officer of the Grand Fleet. In 1919 he became Director-General of the Medical Department of the Royal Navy, and held that post for four years. He received the MVO in 1906, in 1912 the CVO, in 1918 the CB, in 1919 the KCMG, and in 1922 the KCB.

He also received the Distinguished Service Medal of the United States Army and the second class of the Russian Order of St Stanislaus. In 1923 he was appointed Honorary Surgeon to the King, and in 1926 received a Good Service pension, left vacant by the death of Sir Henry Norbury.

After his retirement Sir Robert Hill lived for some years in London at Whitehall Court. In 1929 he went to reside at Henley where he took an active interest in local affairs. He was vice president of the Henley Branch of the British Legion and at one time president of the Henley Golf Club. He was also a director of the Star and Garter Home at Richmond. Queen Mary never lost touch with him and the last letter he was able to understand was one from Her Majesty written only a few days before his death, which gave him the utmost

pleasure, she wrote to him every Christmas. He never married, but had a very large circle of close friends.

The funeral on April 22 at Remenham Church, near Henley, was attended by the First Sea Lord, Lord Chatfield, the Medical Director General, Surgeon Vice Admiral P T Nicholls, Admiral Sir John Green, and Surgeon Rear-Admiral H C Whiteside.

Sir Humphry Rolleston writes:

Robert Hill was a keen athlete, especially as a Rugby football player at the Middlesex Hospital, and this was one of his special qualifications for the post of staff surgeon at Osborne College when it first opened. There he had a busy time, for many of the cadets who had not previously had some of the infections of child

hood were attacked by measles and so forth, thus causing much anxiety among their parents and some undue public notoriety. An epidemic of conjunctivitis, common in all schools, was very seriously taken as "pink eye," and ingeniously if erroneously, ascribed by the public to the stables of the Osborne dormitories over or close to the stables of Queen Victoria at Osborne House, the connexion with horses was that an outbreak of so-called pink eye among horses in South Africa had occurred in the Boer War.

Hill held many appointments. In 1907 he was appointed operating surgeon at the Naval Hospital, Bight, Malta, and at the outbreak of war was in medical charge of the Marine Depot at Deal, where cases of cerebrospinal fever occurred early in 1915. In 1916 he became Principal Medical Officer to the Grand Fleet, being on the staff

of the Commander-in-Chief, first Lord Jellicoe in the *Lion Duke* and later Lord Beatty in the *Queen Elizabeth*. He had been awarded accelerated promotion at an earlier period in his career, and as he was not appointed to any of the main Royal Naval Hospitals—Haslar, Plymouth, or Chatham—after the war, but was promoted Director-General of the Medical Department of the Admiralty with the rank of Surgeon Vice Admiral (1919-23), he was retired early, before the age of 60. But he then freely gave his services to the Red Cross and to other charitable objects, especially for ex-Servicemen.

An able surgeon and efficient administrator, with an extremely friendly, cheerful, and approachable personality, who often kept in touch with former patients, he had troops of friends whom he was always delighted to see and to help. He deservedly received many honours.

a clubbable companion and was much in request on the committees of the Army and Navy Club. For some months he had been in failing health and his appearance had made his friends anxious.

### JOHN BRIGHT BANISTER MD

FRCP FRCSEd FCOG

Senior Obstetric Physician, Charing Cross Hospital

Mr J Bright Banister, the well known London obstetrician and gynaecologist, died suddenly on April 16 aged 55. His principal appointments were those of obstetric physician and lecturer on obstetrics and gynaecology at Charing Cross Hospital and chairman of the Medical Committee, surgeon to the Chelsea Hospital for Women and consulting obstetric surgeon to Queen Charlotte's Maternity Hospital.

The eldest son of Howard C Banister of Tunbridge Wells, he was born at Blundellsands on April 3 1880 and from Merchant Taylors School Crosby, Lancashire went to Jesus College Cambridge and gained honours in the Natural Sciences Tripos of 1901. He then entered as a medical student at Charing Cross Hospital and after taking his M.A. qualified as L.S.A. in 1906, two years later he graduated in medicine at Cambridge, proceeding MD in 1909. He obtained the FRCSEd in 1913 and was elected a Fellow of the Royal College of Physicians of London in 1928, having held the membership since 1910. At the foundation of the British

College of Obstetricians and Gynaecologists in 1929 Banister was one of its first Fellows and he became later a member of the Council. His career in that specialty began in the post of resident obstetric officer at Charing Cross Hospital in 1907 after he had been house surgeon and house physician there. This was followed by experience as registrar and pathologist at Queen Charlotte's registrar at the Chelsea Hospital for Women and obstetric registrar and tutor at Charing Cross and afterwards as a member of the visiting staff of all three institutions. He was also gynaecologist to the Prince of Wales Hospital, Tottenham from 1912 to 1924. At various times he examined in midwifery and diseases of women for the Universities of London, Cambridge and Aberdeen for the English Conjoint Board and for the Central Midwives Board. He served in France and Egypt during the war as *medecin en chef* Anglo-French Hospital Le Treport and as surgical specialist No 17 British General Hospital Alexandria. Besides his long association with three large London hospitals Banister was honorary gynaecologist to the Northwood Memorial Hospital and the Norwood Cottage Hospital and obstetric surgeon to the Florence Nightingale Hospital in Lisson Grove. At the Bath Meeting of the British Medical Association in 1925 he served as honorary secretary of the Section of Obstetrics and Gynaecology and ten years later was vice president of the same section at the Melbourne Meeting. He had also been vice president of the Obstetrical Section of the Royal Society of Medicine. In addition to many papers in the medical journals Banister was part author of *Queen Charlotte's Textbook*

of Obstetrics and author of a *Manual for Midwives* which has gone through several editions.

At the memorial service in St Martin in the Fields on April 20 the Council of the British Medical Association was represented by Sir Ewen Maclean, President of the British College of Obstetricians and Gynaecologists.

Mr Victor Bonney writes:

The death of John Bright Banister deprives the profession of a fine gynaecologist and obstetrician and a most genial and lovable man. He and I first became acquainted in 1909 when he came to Chelsea Hospital for Women as registrar. Those who only knew him of later years will be surprised to learn that at that time he was a quite slender youth looking less than his age. His duties as registrar were so well carried out that when a vacancy on the honorary staff occurred in 1913 he was elected junior assistant surgeon. The war came horribly afterwards and during those troublous years I saw but little of him as our paths diverged. But after it was over and the non-war staff had come together again the recognition that a period of collegialship on which I shall always look back with pleasure.

Besides being on the staff of Chelsea Hospital for Women Banister was also attached to Charing Cross and Queen Charlotte's Hospitals and other smaller institutions and his reputation steadily grew until he became one of the best known exponents of gynaecology and obstetrics in Great Britain. As a surgeon he was gifted with what is sometimes called a beautiful pair of hands, dexterous and gentle with the result that he carried through the most severe operations with a minimum of shock to his patient. By temperament he was always cool and steady, difficulties did not discourage him and he unforeseen left him unweary. Beyond his professional attainments he will be missed for his personal qualities of good humour, kindness and generosity. No man has ever been freer of envy and uncharitableness. Finally I would pay tribute to his fine courage which enabled him knowing the menace to carry on steadfastly till the end.

Two junior colleagues (F C and C D R) write:

An inspiring leader has been called to our midst at a time when our profession is in serious need of guidance.

J B was a great man and a very great gentleman. There are many of us who will sorely miss his personal encouragement, his wisdom and his ready sympathy. He never spared himself in working for others although the calls upon his time and energies were unbounded. His capacity for generous endeavour seemed unlimited and in every situation his control was perfect. It is not long since he himself quoted Shelley's lines in writing of his old chief, Arthur Giles:

Man who man would be  
Must rule the empire of his clime in it  
Must be supreme establishing his throne  
On vanquished will quelling the anarchy  
Of hopes and fears being first of love

And now it falls to our sad lot to reflect that a great chief was so animated throughout his honourable career. It is often said of a man who is dead that he never fails of anyone. In the case of Banister this is a true statement whatever the conditions. Never really to be a shroud though a cruel judge of human nature. Perhaps he suffered too much too gladly. For that he will be missed in the hereafter but to him is a virtue that is up to take its toll on earth. However over a dead he may have been—and at times he must have felt despair and tired—he always took the trouble to understand people and

their moods, and to encourage every individual with whom he came in contact, whether an exacting patient or an argumentative colleague. In this respect gynaecological and obstetric practice is a particularly trying pursuit; reason alone rarely prevails. Quite apart from his technical skill, he was a man of profound clinical judgment, he had insight and that flair, born of imagination and experience, which is given to very few in these days of medical confusion. He was an inspiring teacher and a remarkably fair examiner, beyond that he was a healer in the very best sense of the word. This is a rare combination. Banister's advice and opinion will be sorely missed in the council chamber of the British College of Obstetricians and Gynaecologists and the Central Midwives Board, and in the Court of the Society of Apothecaries. He exercised his great talents in many capacities, wherever he served, he served with the utmost distinction and with all his heart and soul. Some of us will feel his loss most keenly at the Chelsea Hospital for Women, where, as senior surgeon, an ideal chairman, and a never-failing friend, he ruled and directed with dignity and an entire absence of friction. 'J B' was a good and sincere Mason, an officer of Grand Lodge. There are thousands within and without the ranks of Freemasonry who will mourn his death.

[The photograph reproduced is by Elliott and Fry, Ltd.]

#### J G COOKE, OBE, MB, CHB

By the death of Dr John Galwey Cooke, at the age of 78 years, Londonderry and the North of Ireland generally has lost a medical man of outstanding ability and personality. Dr Cooke belonged to an old South of Ireland family; his father, the Rev Ambrose Cooke, being rector of Thomastown in Co Kilkenny. He received his medical education at Trinity College, Dublin, where after receiving the degree BA he graduated in medicine in 1887 with the degrees of MB, ChB. After acting as house-surgeon for some time and obtaining the LM of the Rotunda Hospital he accepted the post of resident assistant surgeon to the Londonderry City and County Infirmary under the late Sir William Miller. On the death of Sir William Dr Cooke was appointed surgeon to the hospital—a post he filled with distinction until his resignation in 1920.

He was always keenly interested in his profession, and took an active part in everything pertaining to its welfare. He was a Fellow of the Royal Academy of Medicine in Ireland and an ex-president of the Londonderry Medical Society. He was deeply interested in the affairs of the British Medical Association having acted as honorary secretary to the Derry Division for over thirty years and having been a president of the former Ulster Branch, and in earlier years secretary, vice-president, and president of the Londonderry and North-West of Ireland Branch. It was during the great war that Dr Cooke's energy, organizing ability and sympathy got full scope, for during this period shipwrecked and injured sailors were constantly being brought to the hospital in Derry for treatment and care. For the magnificent work he did so truly and generously at this time he received the OBE—an honour to which he was well entitled.

With his passing yet another of the good old school of doctors has gone—a type that is, unhappily, rapidly diminishing. Dr Cooke will always be remembered by those who were privileged to be numbered among his friends for his kindness, his courteousness and his genuine sympathy. He is survived by his sister, to whom the sympathy of a large circle is extended.

#### W H DOLAMORE, FRCS, LDS

We regret to announce the death on April 19, at the age of 74 of Mr William Henry Dolamore, a distinguished member of the dental profession who did much to strengthen its position and increase its value to the public. Entering as a student at the Royal Dental Hospital, Leicester Square, he won the Saunders scholarship in 1888 and obtained the LDS. He then studied medicine at St Mary's Hospital, and after qualifying MRCS and LRCP in 1892 was appointed dental surgeon to the London Hospital. He was a member of the staff of the Royal Dental Hospital for more than thirty years, and returned to St Mary's Hospital as dental surgeon. From 1912 to 1922 he was a member of the Board of Examiners in Dental Surgery of the Royal College of Surgeons of England, and in recognition of these and many other services he was elected FRCS in 1933. He had also been external examiner in dental surgery for the Universities of Liverpool and Leeds. Mr Dolamore did invaluable work early in the first decade of the present century as honorary secretary of the British Dental Association, and in 1915-18 was president. When the Dental Board of the United Kingdom was set up in 1921 under the Dental Act of that year the Minister of Health appointed him a member, and three years later, when that office lapsed, he was elected to the Board by qualified dentists in England and Wales, retiring in 1934. Throughout the whole period of thirteen years he was treasurer of the Dental Board and an additional member of the General Medical Council under the Dentists Act, 1921, appointed by the Privy Council. Mr Dolamore joined the British Medical Association in 1895, and was vice-president of the Section of Odontology at the Annual Meeting in London in 1910.

Supplementing our obituary notice of Dr JAMES GODDING (April 16, p 875), 'T B B' sends the following tribute: 'I had every opportunity of appreciating his worth as a man and his very high degree of administrative ability when he was in command of No 17 General Hospital, Alexandria, Egypt, in 1917 and 1918. I was ADMOS at Alexandria throughout the war, and No 17 was the largest of our general hospitals there. From an establishment of 2040 beds it had expanded to 3,500 beds, and remained at that figure during the period of Godding's command. Never had I a moment's anxiety as to the successful, smooth, and efficient working of that very large unit while he was there. His training as a barrister and his medical work in various offices, including that of coroner at the Port of London, were invaluable in the administration of this very large and important war hospital. The GOC Alexandria fully appreciated his value, and on several occasions when he had a difficult court martial or a complicated court of inquiry on hand he would tell us that he must borrow Godding again to be president as he was far the best man he had in his command for the job. It can have fallen to the lot of few medical men to command a battalion in France and Egypt with distinction, and then to administer a hospital of this size with such signal success as to earn four mentions in dispatch. I am sure that all members of the staff of No 17 GH will join with me in mourning the loss of a true friend and a very exceptional personality.'

Dr HARRY STARK of Stoke Newington, London, died on April 19 as the result of septic blood infection contracted from a patient. He had been under treatment for several weeks at the Royal Northern Hospital. Born in 1902 Dr Stark was a student at St Bartholomew's Hospital and qualified MRCS, LRCP in 1929. At St Bart's he had been casualty medical officer and clinical assistant in the ear, nose, and throat department. He also served as house physician, house surgeon, and resident.

medical officer at the Royal Waterloo Hospital for Children and Women. He was a member of the City Division of the British Medical Association and had practised for some years at Stoke Newington Common holding the posts of assistant school medical officer under the L.C.C. divisional medical officer for the British Home and Hospital for Incurables and medical officer in charge of the Leistonstone Children's Homes. Dr Stark's untimely death at the post of duty has caused grief to all his patients.

Mr CHARLES EDWIN TRUMAN M.R.C.S. L.D.S. for more than thirty years surgeon-dentist to the King's Household died at Upton Slough, on April 14 aged 88. His early education was at Geneva. From Eton he went to Caius College Cambridge to study medicine and thence to St Thomas's Hospital. He graduated B.A. in 1871, proceeded M.A. in 1874 and took the M.R.C.S. diploma in 1875. He then studied dentistry at the Dental Hospital in Leicester Square becoming L.D.S. in 1881 and soon afterwards was appointed to the staff of that institution. Mr Truman was also for many years surgeon-dentist to St Thomas's and on his retirement was elected to the consulting staff and made a governor of the hospital.

Dr EDWARD ERNEST NORTH SLURRIDGE who practised for many years at Knutsford Cheshire died on Easter Sunday at Saffron Walden aged 73. In recent years his sight had failed so that he could not read or write. Dr Slurridge graduated B.A. at Cambridge in the Natural Sciences Tripos in 1886 and after further medical study at St Bartholomew's Hospital took the M.B. and Ch.B. degrees in 1891. Before settling in general practice he was house physician at Barts and assistant house surgeon to the Norfolk and Norwich Hospital. At Knutsford he had been medical officer to the Post Office and a member of the medical staff of the War Memorial Cottage Hospital. He joined the British Medical Association in 1892 and only gave up membership a few months ago.

News has been received in England of the death on March 28 in Cape Town after a short illness of Dr HENRY BRYAN DENSHAM of Stockton-on-Tees, where he had practised for many years before retirement and was consulting surgeon to the Stockton-on-Tees Hospital. Dr Densham was born in 1863 and received his medical education at Bristol and Edinburgh graduating M.B. Ch.B. in 1887. He joined the British Medical Association in 1892 and had long been a member of the Stockton Division. When the Association held its Annual Meeting in Newcastle-upon-Tyne in 1921 he was vice president of the Section of Proctology.

We regret to announce the death at Quinta do Val Madeira of Dr MICHAEL GRABHAM who was president of the Jamaica Branch of the British Medical Association in 1926-7 and had been a member for forty-seven years. He was the elder of the two sons of Michael Comport Grabham M.D. F.R.C.P. the patriarch of Madeira who died three years ago at the age of 95 and his mother was Mary Blandy, a member of the well-known family in that island. He studied medicine at Cambridge and St Thomas's Hospital graduating M.B. B.Ch. in 1891 and taking the English Conjoint diplomas in the same year. Dr Grabham practised for many years in Jamaica before returning to Madeira.

The annual malaria control course for laymen (engineers, planters, etc.) will be held at the Ross Institute of Tropical Hygiene (Keppel Street W.C.1) beginning Monday June 27 at 10 a.m. It will be under Sir Malcolm Watson, director of the Institute and will last five days. The course is free and applications to attend should be sent in as early as possible to the organizing secretary at the above address.

## Medico-Legal

### IRREGULAR RESTRAINT OF DEFECTIVE

The certification of mental defectives does not often raise legal questions of the same magnitude as the certification of persons of unsound mind, but the liberty of the subject is safeguarded with equal strictness. The Mental Deficiency Act 1913 provides that when a defective is certified the order under which he is sent to an institution or placed under guardianship shall expire at the end of one year from its date unless it is continued in the way which is laid down. At the end of the year the Board of Control considers the medical reports on the case and may make an order which will be valid for another year. After that a succession of orders may be made each covering five years. A recent decision by the Court of Appeal lays down that these periods must be construed strictly and that if an order is not renewed within a period of its operation the renewal is invalid.

A mental defective was certified on June 11, 1929. On June 23, 1930 a continuance order was made and in 1931 another continuance order was made on June 29 which purported to continue the order till June 24, 1936. A further order was made on July 6, 1936.

He applied to the Divisional Court of the King's Bench Division for a writ of *habeas corpus* alleging that he had been unlawfully restrained since June 24, 1931 because on that date the order under which he was restrained expired and the continuance order made on June 29 could not have any effect. The Divisional Court would not grant the writ but the Court of Appeal decided that it should be granted. Lord Justice Slesser, in giving the judgment of the court, said that the Act seemed unambiguous in its terms. The language was not such as to permit any consideration of the convenience or inconvenience which might be felt in operating the Act by the Board of Control. The Act gave no power to make an order for more than a year. The time for the continuance order to be made would have been June 24, 1931. For the five or six days afterward it the detained man had walked out of the institution no one could have pointed to any authority under which he could properly have been detained. It was impossible to say that he was still detained because no order had been made in 1931 within the period laid down by the Act. Another reason to allow the appeal was that the Commissioners under the Act had to satisfy himself that the appellant was mentally defective did not come to his final decision until July 7, 1931. Lord Justice Clauson and Mr Justice Goddard agreed. The Attorney General who had appeared for the Board of Control said that Mr Winterlood had been released on licence and was not therefore now being detained.

## The Services

### INDIAN MEDICAL SERVICE DINNER

The annual dinner of the Indian Medical Service will be held at the Trocadero Restaurant, London, on Tuesday, June 14, at 7.15 p.m. when Major General E. W. C. B. and C.I.E. OBE, the Director General I.M.S., will preside. Tickets may be obtained from the Honorary Secretary, Major S. Thomas Care Evans, Hammerstein Hotel, Pall Mall, London W.12.

### ARMY MEDICAL SERVICES

Colonel O. W. McSteeh, D.S.O. OBE, late R.A.M.C., has been appointed Deputy Director General Army Medical Services. War Office vice Colonel F. Clement, D.S.O. late R.A.M.C. who has been promoted to Major General.

R. Board of Control, ex parte Winterlood, T. 1938, April 9, 1938.

## Universities and Colleges

### UNIVERSITY OF OXFORD

The following notice was published in the *Oxford University Gazette* of April 20

#### FIRST EXAMINATION FOR THE DEGREE OF B M

The Board of the Faculty of Medicine gives notice of the following changes in the regulations for human anatomy

(1) (*Examination Statutes* 1937, p 318) for 'Every candidate for the Examination in Human Anatomy whole body once' substitute 'Every candidate for the Examination in Human Anatomy must produce a certificate, signed by Dr Lee's Professor of Anatomy or by his deputy showing that he has dissected the whole body once and that he has attended a course of embryological histology

(2) For the present form of Certificate I (p 321) substitute

#### 1 PRACTICAL HUMAN ANATOMY

*I certify that \_\_\_\_\_ has dissected the whole body once and that he has attended a course of embryological histology at \_\_\_\_\_ from \_\_\_\_\_ to \_\_\_\_\_*

Signature\* Name  
Qualification  
Address  
Official Position  
Date

\* This Certificate must be signed by Dr Lee's Professor of Anatomy or by his deputy

The above changes will come into operation on October 1, 1938 except that until the end of December 1939, the Board will be prepared to exempt from the requirement of having attended a course of embryological histology any candidate for whom it is satisfied that the requirement constitutes a hardship

### UNIVERSITY OF LONDON

A public lecture, on 'Some Aspects of the Heart Sounds in Normal and Pathological Conditions' will be given by Dr E Braun-Mcnenendez director of circulatory investigations, Institute of Physiology in the Faculty of Medical Sciences, Buenos Aires in the department of physiology pharmacology, and biochemistry of University College, Gower Street, W C, on Tuesday May 3, at 5 p.m. The chair will be taken by Professor C Lovatt Evans FRS. The lecture is open, without fee or ticket to students of the University and others interested in the subject

### UNIVERSITY OF DUBLIN

#### SCHOOL OF PHYSIC TRINITY COLLEGE

The eighth John Mallet Purser Lecture will be delivered by Sir Henry Dale FRS Director, National Institute for Medical Research Himpstead London on Wednesday, May 4 at 5 p.m. in the physiology theatre. The subject of the lecture will be 'Chemical Agents Transmitting Nervous Excitations'. The Provost of Trinity College will take the chair

### UNIVERSITY OF GLASGOW

A graduation ceremony was held on April 23, when the following degrees among others were conferred

## Medical Notes in Parliament

In the House of Commons on April 26 the Chancellor of the Exchequer, in opening the Budget, briefly referred to the medicine stamp duty. He said that a committee of the House which considered this subject made a valuable report last year, but it had not yet been possible to arrive at conclusions on all the complex issues involved. It was his intention that a decision should be reached before next year's Finance Bill.

Sir John Simon proposed that the general rate of income tax should be increased by 6d to 5s 6d in the £, the rate on the first £135 remaining at the present level of 1s 8d. He also proposed an increase to 9d a gallon in the petrol tax on light hydrocarbon oils and on power alcohol and also on heavy oils used in road transport. The tea duty was increased by 2d a pound. Resolutions giving temporary authority for these imposts were carried by the House the same night.

### London Hospitals and A R P

On April 26 Colonel NATHAN asked the Home Secretary what directions had been given or were contemplated for the information of the general and special hospitals in London as to the measures they should take for dealing with patients and the functions they were desired to fulfil in the event of air raids. Mr GEOFFREY LLOYD replied that instructions as to the methods of dealing with gas casualties were being given to the medical and nursing staffs of London hospitals as part of the Home Office scheme of medical anti gas instruction. A handbook on the structural protection that could be arranged in hospitals for the additional safety of staff and patients would shortly be issued. As regards the last part of

this question this must await the completion of the survey which is being undertaken by the Minister of Health.

Colonel NATHAN said he had a letter from the Air Raid Precautions Department of the Home Office stating that pending the completion of the survey of hospital accommodation throughout the country it was not possible definitely to allocate to individual hospitals the parts they might be called upon to take. That letter was addressed to a hospital adjacent to the House of Commons and was dated May 19.

Mr LLOYD: We must have a little further information. I do not think it will be necessary for the survey to be completed all over the country before dealing with the London hospitals.

Sir FRANCIS FREMANTLE suggested that instruction on medical work in air raids should be given at the medical schools.

## Medical News

The gold medal of the Royal Society of Medicine has been awarded to Mr Wilfred Trotter F.R.S., Director of the Surgical Unit at University College Hospital. This is the seventh award of the medal which is given triennially to a scientist man or woman who has made valuable contributions to the science and art of medicine. The previous holders of the medal have been Sir Almroth Wright, Sir F. Gowland Hopkins, Dr J. S. Haldane, Sir Henry Head, Sir Thomas Barlow, and Sir Archibald Garrod.

The Manson Medal of the Royal Society of Tropical Medicine and Hygiene has been awarded to Major General Sir Leonard Rogers K.C.S.I., C.I.E., F.R.S., I.M.S. (ret.) and will be presented at the annual general meeting of the Society on June 16. The medal is awarded triennially to the living author of such work in any branch of tropical medicine or tropical hygiene as the council may consider to be deserving of the honour.

A special lecture describing the anti-leprosy campaign in Brazil will be given in the main lecture theatre of the London School of Hygiene and Tropical Medicine (Keppel Street, Gower Street, W.C.) to-day (Friday, April 29) at 5 p.m. by Dr H. C. de Souza Araujo, secretary of the International Centre of Leprology in Rio de Janeiro. All interested are invited to attend.

A sessional meeting of the Royal Sanitary Institute will be held at Cardiff City Hall on Friday, May 6, at 5 p.m. in conjunction with the Welsh Branch of the Society of Medical Officers of Health and the South Wales and Monmouthshire Centre of the Sanitary Inspectors' Association, when discussions will take place on 'The First Municipal Asthma Clinic' to be opened by Dr D. A. Williams and on 'The Place of the Public Health Department in Relation to the Council Housing Estate' to be opened by Mr J. A. Glover.

The Oxford Ophthalmological Congress will open this year on the evening of Wednesday, July 6, at Keeble College, and the scientific sessions will be held on the three following days. On July 7, Dr Bernard Chavasse will introduce a discussion on Ocular Palsies. The Dyne memorial lecturer is Professor A. von Szily of Munster, whose subject is 'The Contribution of Pathological Examinations to the Elucidation of the Problems of Cataract'. A number of papers have been promised by other ophthalmologists from abroad, and Dr H. M. Traquair will open a discussion on Anaesthesia in Ophthalmic Surgery. Applications for membership forms and for full details of the Congress should be sent to the honorary secretary and treasurer, Dr F. A. Anderson, 12 St. John's Hill, Shrewsbury.

The ninth medical conference of Aix les Bains will be held on May 22, when a paper will be read on 'Somatic Neuralgias and their Treatment' by Dr Jacques Fournier. Further information can be obtained from Dr Lelong, Société Médicale d'Aix les Bains, Rue de Liège, Aix les Bains.

A bronze medal known as the Heberden Medal is awarded annually to a registered medical practitioner who in the opinion of the referees appointed by the Heberden Society has carried out the best work in the British Isles on the investigation of the rheumatic diseases. The recipient will be invited to deliver the Heberden Lecture, which should comprise a review of the work carried out for the award of the medal. The first award will be made in January, 1939, to the president of the society, Dr Matthew Rav, with Dr C. W. Buckler and Dr Mervin Gordon F.R.S. Published work should be submitted in the first place to the secretary, Dr Kenneth Storey, 18 Chesterfield House, Chesterfield Garden, Lorton, W.I.

We are informed that as the president of the West Kent Medico-Chirurgical Society has left London there will be no president's address this year. Mr Miles L. Fotherby will give an address on 'Some Common Otological Conditions: Aids to Their Diagnosis and Treatment' before the Society at the Miller General Hospital, Greenwich, S.E., on Friday, May 1, at 8.45 p.m.

Fifty years ago on May 5, 1888, Sir J. Spence Wells, B.F.R.C.S., published in the *British Medical Journal* 'Notes on a Visit to Pilsen and reports of his paper on the bath to visitors at that famous Czechoslovak spa. A short account of the Pilsen bathing establishment with its mud baths appeared in the *British Medical Journal* of June 19, 1927.

On Monday, April 25, Lord De By opened the new x-ray department and the extensions to the out-patient department at the Christie Hospital and Holt Radium Institute, Manchester. The new treatment equipment consists of four x-ray tubes on the continuously evacuated type, each operating at 100 kV. The control desks are situated outside the treatment room.

The Middlesex Hospital Medical School's new athletic ground at Chislehurst has been presented by Sir Edward Meyerstein and will be available for games on April 10. It consists of over eighteen acres and a large pavilion with two floors is nearing completion. This new ground will provide students with increased facilities for sport. It is situated on the Foxbury site and for those not going by road there is a frequent service of trains to Chislehurst from Charing Cross, Cannon Street, and London Bridge station, and the ground can be reached by a bus service passing Chislehurst and Bickley stations.

The Listerian Society of King's College Hospital Medical School is holding a Medico-Legal Trial on Wednesday, May 4, at 8.15 p.m., presided over by His Honour Judge Earengay.

In our advertisement columns this week the Staffordshire Mental Hospitals Board invite applications for the appointment of Medical Superintendent to the County Mental Hospital, Stafford. The salary is £1,100 per annum.

Dr W. E. Bennett, who has completed just over half a century as medical officer of health for Oxford, was presented on April 21 with a gold tourmaline pen and pencil to present and past members of the Council and officials in recognition of his long service.

Sir James Crofton B. O. F.R.S., who died on January 31, aged 97, left a will valued at £105,078, his net personal estate at £102,221.

The Grenfell Association of Great Britain and Ireland (66 Victoria Street, S.W. 1) announce that a new medical Sir Wilfred Grenfell's medical work in Labrador and Newfoundland will be held at 72 Draxton Gardens, S.W. 9, on May 25 and 26, from 10 a.m. to 10 p.m. each day.

Mr and Mrs Erich Haug, of a Secretary, have given £25,000 to the Norwegian Radium Institute for the building of a new medical building for cancer research. The block will have a first floor for men and twenty-five for women and the nurses' home will be extended.

Dr H. C. Squares has been appointed Consulting Physician to the Sudan Government.

A severe epidemic of smallpox has been reported from Havre.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended April 16, 1938

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland Median values for the last 9 years for (a) and (b)

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for (a) The 125 great towns (123 in 1937) in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns (9 in 1937) in Northern Ireland

A dash — denotes no cases, a blank space denotes disease not notifiable or no return available

§ Includes primary form in figures for England and Wales (London (administrative county) and Northern Ireland

## EPIDEMIOLOGICAL NOTES

## Enteric Fever

There has been an increase of enteric fever in England and Wales during the week under review—29 cases being notified as against 17 in the previous week and 25 in the corresponding week last year. The increase is largely due to the outbreak of paratyphoid fever in the Cardiff district where 12 cases were notified. 10 in Cardiff itself, 1 in Merthyr Tydfil and 1 in Llantrisant. Elsewhere notifications were widely scattered over England and Wales: 2 in Birmingham, 2 in Coseley (Staffs) and among the large towns 1 each in London, Birkenhead, Bristol and Leeds.

## Diphtheria and Scarlet Fever

Notifications of diphtheria dropped fairly steeply in England and Wales (London sharing in the decrease) and Eire while small increases were reported from Scotland and Northern Ireland. The numbers for England and Wales are still in excess of the median value for the last nine years while those for London are considerably less. In all four countries scarlet fever appears to be less prevalent than in the previous week but in England and Wales and in Eire it is more prevalent than in the corresponding week last year. In England and Wales the number is greater than the median value for the last nine years but in London it is less.

## Measles and Whooping-cough

In the 125 Great Towns in England and Wales there were 54 deaths from measles compared with 26 in the previous week of these 14 (15) occurred in London, 4 (4) in Manchester, 4 (1) in West Hartlepool, 2 each in Kingston upon Hull, Crosby, Bolton, Birkenhead, Reading, Portsmouth, Dagenham. The figures in parentheses refer to the numbers in the previous week. The measles epidemic in London appears to be subsiding: 996 cases were reported from the LCC elementary schools compared with 1,895 and 2,095 in the two immediately preceding weeks. The average daily admissions to the LCC fever hospitals dropped from 75 to 74 while the number of cases of measles under treatment in these hospitals on April 15 was 2,220 compared with 2,241 on April 8 and 2,339 on April 1. On the same day there were under treatment in the LCC fever hospitals 1,140 (1,160) cases of diphtheria, 802 (843) cases of scarlet fever, 264 (291) cases of whooping-cough. The figures in parentheses refer to the numbers recorded in the previous week. Notifications in the eleven metropolitan boroughs in which measles is notified were for the week ended April 16: 734 (833) distributed as follows: Battersea 92 (128), Bermondsey 42 (88), Finsbury 39 (27), Fulham 68 (41), Greenwich 82 (99), Hampstead 24 (55), Lambeth 162 (188), St Pancras 94 (110), Shoreditch 26 (31), Southwark 60 (115), Stepney 45 (51). The figures in parentheses denote the numbers in the previous week. In Scotland 724 cases of measles were reported compared with 1,044 in the previous week, the figures for Glasgow were 285 (349), Aberdeen 204 (81), Edinburgh 65 (65), Dundee 63 (179), Paisley 25 (42). The figures in parentheses denote the numbers recorded in the previous week. During the week under review there were 33 deaths from measles in the 16 principal towns of Scotland compared with 25 in the previous week, of which 11 each occurred in Glasgow and Dundee and 2 each in Edinburgh, Clydebank, Coatbridge and Falkirk. In Northern Ireland 24 cases of measles were notified all in Belfast compared with 30 in the previous week. Four deaths from measles occurred in Belfast 1 more than in the previous week. Whooping-cough appears to be on the increase in Scotland and Northern Ireland—67 compared with 42 and 11 compared with 4 respectively—but no deaths were reported. The number of deaths in England and Wales and London was practically the same as in the previous week.

## Typhus

During the week ended April 2 there were in Algeria 82 cases of typhus (compared with 67 in the previous week) of which 65 occurred in Constantine and 16 in Algiers. During the week ended April 9 107 cases were reported in Egypt with 12 deaths occurring both in the towns and in widely scattered districts. During the same week there were in Morocco 248 cases of typhus with 25 deaths of these cases 57 were in Casablanca (6 deaths), 25 in Casablanca (7 deaths), 29 in Rabat (4 deaths), 2 in Fez (1 death). During the same week there were 61 cases of typhus in Tunisia widely scattered in the civil districts of the northern territories.

## Psittacosis

At an inquest on April 20 on William James Sprunt a relief keeper at the London Zoo the jury found that Sprunt died from psittacosis contracted during the course of his employment. It was stated that blood tests on the four keepers who tell ill about the same time were negative for psittacosis. Apparently the source of infection was a consignment of parrots brought from South America and the West Indies by Lord Moynihan. Those which did not die have since been destroyed. This is the first time that psittacosis has appeared in the Zoo for 100 years and the parrot house is to remain closed until the authorities are satisfied that the public run no risk on being readmitted. A leading article on psittacosis appeared in the *Journal* of April 2.

## Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish no notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1 on receipt of proof. Authors over seas should indicate on MSS. if reprints are required as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager, Office of the *Journal* and communication with reference to subscriptions should be addressed to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

THE TELEPHONE NUMBER of the *British Medical Association* and the *British Medical Journal* is EUSTON 2111.

THE TELEGRAPHIC ADDRESSES are:  
EDITOR OF THE BRITISH MEDICAL JOURNAL: 4 Wescei, London.

SECRETARY: *Medicine* Westcott, London.  
The address of the B.M.A. South of the Eire is 7, Drumahogue Garden, Edinburgh (telegrams: 4511) and of the Irish Free State is 2, 61 Edinboro, and of the Oireachtas is 1, 10, 15, 20, 25, 30, 35, 40, 45, 50, 55, 60, 65, 70, 75, 80, 85, 90, 95, 100, 105, 110, 115, 120, 125, 130, 135, 140, 145, 150, 155, 160, 165, 170, 175, 180, 185, 190, 195, 200, 205, 210, 215, 220, 225, 230, 235, 240, 245, 250, 255, 260, 265, 270, 275, 280, 285, 290, 295, 300, 305, 310, 315, 320, 325, 330, 335, 340, 345, 350, 355, 360, 365, 370, 375, 380, 385, 390, 395, 400, 405, 410, 415, 420, 425, 430, 435, 440, 445, 450, 455, 460, 465, 470, 475, 480, 485, 490, 495, 500, 505, 510, 515, 520, 525, 530, 535, 540, 545, 550, 555, 560, 565, 570, 575, 580, 585, 590, 595, 600, 605, 610, 615, 620, 625, 630, 635, 640, 645, 650, 655, 660, 665, 670, 675, 680, 685, 690, 695, 700, 705, 710, 715, 720, 725, 730, 735, 740, 745, 750, 755, 760, 765, 770, 775, 780, 785, 790, 795, 800, 805, 810, 815, 820, 825, 830, 835, 840, 845, 850, 855, 860, 865, 870, 875, 880, 885, 890, 895, 900, 905, 910, 915, 920, 925, 930, 935, 940, 945, 950, 955, 960, 965, 970, 975, 980, 985, 990, 995, 1000.

## QUERIES AND ANSWERS

## Income Tax

*D. A. H. P. Practitioner*

H. C. M. explains that his father was the proprietor of a sole practice up to his death on August 12, 1917. At that date to November 1, 1917 the practice was carried on by the executors who employed him as a partner. H. C. M. has carried on the practice as a partner since the practice was assessed on the estate and the income tax authorities are calling for particulars of the income tax (a) between January 1 and August 12, and (b) after August 12 to the present time and a statement of the amount of the income tax still outstanding. Are these receipts liable to income tax?

In our view the position is as follows: As regards (a) the amount of the receipts is required to assess the

profits to the date of death and should be supplied. From August 12 to November 1 the executors are liable in respect of the profits of that period—if the income tax authorities are willing to accept the amount of the cash receipts as the amount of the *gross* income of that period that is obviously convenient but they can insist on the value of the gross bookings being taken if they desire and that course is the one which is legally correct. From November 1 onwards

H C M is personally liable and should base his return on bookings and on cash receipts. It will be seen from the above that the only way in which cash received after January 1 1937 can come into the calculation is for the special purpose of calculating the profits to August 12, 1937 and that cash received after that date does not affect the income tax figures. The deceased has been assessed in respect of his earnings up to April 5 1937, and the only further liability of the executors is for the period to August 12 1937. Any cash received after that date merely represents the in gathering of profits on which tax has been paid, and is capital so far as the estate is concerned.

#### Retirement from Practice

NEWCASTLE inquires what further payments of income tax, if any a practitioner will have to make if he retires at the end of 1938 after paying all tax due up to and including the July 1938 payment.

\*\* The July 1938 payment represents the final instalment of the tax assessable for the year to April 5 1938. In such circumstances the practitioner will have to account for tax in respect of his earnings for the further period of nine months to December 31 1938, and that tax will be due to be paid in January and July 1939.

#### Motor Car Depreciation

MOTORIST bought a car on March 25 1936 for £325 and his running expenses including insurance but not depreciation for the two following years were £133 and £102 respectively. For insurance purposes the car was valued at £260 in March 1937 and £160 in March, 1938. What can he claim?

\*\* It has to be borne in mind that the only depreciation allowable for income tax purposes is that arising by reason of wear and tear. In practice this is calculated in the case of motor cars at 20 per cent of the written down value as shown below.

Value at April 5, 1936	£325	
Depreciation at 20 per cent	£65	
Add statutory additional 10 per cent	£7	
Allowance for 1936/7		£72
Value as at April 5 1937 £325-£65=	£260	
Depreciation at 20 per cent	£52	
Add statutory additional 10 per cent	£5	
Allowance for 1937/8		£57
Value as at April 5, 1938, £260-£52=	£208	

The claim for travelling expenses should therefore be—

1936/7 £133+£72=£205  
1937/8 £102+£57=£159

If however the car has been used for non professional purposes some restriction of these deductions will be necessary.

## LETTERS, NOTES, ETC

### Pathology of Robert Burns

Dr WALTER R. BETT writes. The obituary of Sir James Crichton Browne in the *Journal* of February 5 referred to the fact that his mother was highly gifted and that few knew their Burns as she did. In this connexion it may be worth while noting that some ten years ago Sir James wrote a small book of 92 pages published by Hodder and Stoughton (undated) with the title *Burns from a New Point of View* in which he advanced the theory that the poet was not a confirmed drunkard but a painful example of the neglect of rheumatism in early life. His biographers particularly the arch calumniator James Currie who was an ardent prohibitionist and antipathetic to Burns the man though not to the poet insist that his death was caused by exposure through lying asleep in the snow in a drunken condition. Sir James believes that he fainted from heart failure and collapsed just outside the inn after a moderately convivial evening.

### Keesing's Medical Digest

Still another attempt has been made to meet the demand of busy readers for potted information. There are many reasons for this demand the bulk of medical literature in the world increases at an alarming pace each year, at the same time, in spite of the machine those who do work seem to become busier and busier, and this is especially the case with medical men. All this makes it difficult for those who like to be up to date to keep themselves well informed of what is happening. *Keesing's Medical Digest* is an attempt to meet the needs of what must be an increasing number of medical men each year. It consists of short abstracts from well-known medical journals in different parts of the world a diary for the current three months of the year and, what should be a particularly valuable feature, an index which will be kept up to date from month to month. The whole is fitted with loose leaves into a stout cover which will slip quite easily into the coat pocket. This would seem to be a useful venture in medical journalism, and for a subscription of one guinea a year not a very expensive one. The publishers are Keesing's Medical Diet Ltd, 1, Regent Street London, SW 1.

### A Bee-eating Sealyham

Dr J. STEWART RICHARDS (Sussex) writes. I read with interest the annotation in the *Journal* of April 16 (p. 818) on bee venom for arthritis. Many of us have heard of or know personally patients who have submitted themselves to a course of bee stings for rheumatism but the following case seems so exceptional that it is perhaps worth recording. The subject was a dog, a Sealyham aged 6. He was not markedly intelligent but of active habits his main objectives in life being the pursuit of food, tennis balls, and rabbits. At one of my visits to his home he was quite disabled for any active exercise save a painful halting walk, his back and buttock muscles were very stiff and tender and obviously painful. The veterinary surgeon's diagnosis was 'rheumatism,' and mine 'fibrous rheumatism.' The condition was attributed by his owner to a curious habit he had of sitting on a damp spot or sometimes actually in water to cool off the heat of the chase. The stiffness lasted for some months but when I next saw him he had completely recovered. I asked for further information and was told that for a short time before his recovery he had been seen going round the flower beds snapping up bees and eating them. My informant was my niece the owner of the dog, a dog lover and an acute observer. Whatever effect the bee venom by mouth may have had on the disease does not the coincidence of the bee eating and the attack of rheumatism suggest some intuitive impulse in animals, or shall I say empirical knowledge of certain internal remedies for their disorders? In the matter of bee venom have they anticipated the researches of the medical profession? Why do dogs so often resort to eating grass and that of the coarsest kind? Is it for constipation? Cows exhibit under certain conditions much appreciation of a lick of salt. A greedy dog I know after unusual gorging resorted to a sun warmed stagnant pond and drank freely. Almost immediately he vomited copiously and seemed greatly relieved the water was warm and foul enough to act as a potent emetic. I have not read any account of the spontaneous use by animals of internal remedies for their disorders but perhaps this note may elicit information on the subject from some of your readers.

### Fitness Wins

The National Fitness Council has recently issued a 64 page illustrated handbook entitled *Twenty-four Ways of Keeping Fit* (H.M. Stationery Office 2d). The illustrations are well chosen and should stir to activity even the most sluggish and for those interested there is a list of twenty-two Area Fitness Committees.

### Corrigenda

By a printer's error the first line of Dr W. J. Hohmann's letter on the control of sulphanilamide therapy in the *Journal* of April 23 (p. 923) reads 'You have twice been so good as to discuss in the paper.' It should have read 'With reference to Dr A. J. Cokkims's interesting paper.'

Dr F. H. JACOB whose paper 'Four Cases of Menstruation Treated with Prontosil' appeared in the *Journal* of April 23 (p. 887) writes to explain that the drug he used in these cases was prontosil album.

# EPITOME OF CURRENT MEDICAL LITERATURE

## Medicine

### 352 Cerebellar Manifestations in Chronic Alcoholism

A. ADRIAN (*Fla. de Paris* 1937 No 733) who records six illustrative cases in patients aged from 35 to 79 three of whom were men and three women states that cerebellar lesions, with or without clinical symptoms are relatively frequent in the course of chronic alcoholism. Generally speaking alcohol is all the more likely to attack the cerebellum if it has already been affected by some other condition. In a certain number of cases also the organ possesses a constitutional weakness which is aggravated by chronic intoxication. There is a special syndrome in which chronic alcoholism is undoubtedly a factor—namely the cerebellar atrophy with cortical predominance described by Pierre Marie. In cases in which there is a previous history of alcoholism this syndrome develops before 40 years of age while in others it does not occur till much later. In all cases of chronic alcoholism with cerebellar manifestations the patients present symptoms of delirium. The cerebellar symptoms may appear either as the result of an alcoholic excess or after a reduction of the amount of drink taken.

### 353 Insulin Resistance

O. L. V. DE WESSELOW and W. J. GRIFFITHS (*Quart. J. Med.* January 1938 p 17) have studied the responses of a group of clinically dissimilar diabetic patients to the insulin glucose test of insulin sensitivity and conclude that there is no evidence of the existence of two distinct types—instances of insulin sensitivity and resistance merge into a larger group showing an approximately normal response. The type of response is not related to the initial blood sugar level nor to the sex, age, blood pressure, body weight or other clinical feature. Resistance or sensitivity to injected insulin is determined by the general state of metabolism at the time of testing and is probably largely due to the metabolic condition of the liver cell which depends to a large extent on the diet. Adequate carbohydrate in the diet results in proper functioning of the liver and thus in sensitivity to the insulin glucose test. It is possible by means of carbohydrate and insulin to convert a diabetic from the insulin resistant to the insulin-sensitive state. The more nearly the diet and hence the metabolic processes, approach with the help of insulin to the normal the less likely is there to be resistance to insulin. This accounts for the increased tolerance which is often acquired by the diabetic when the carbohydrate in his diet is increased.

### 354 Respiratory Infections and Gastric Ulcer

B. B. CROHN and G. SHWARTZMAN (*Amer. J. Digest. Dis. and Nutr.* January 1938 p 705) consider that infections of the respiratory system—for example, colds, influenza, pleurisy, pneumonia, etc.—bear a causal relationship to recurrences of gastric ulcer and especially to haemorrhage. During February and March 1937 when influenza was prevalent and severe they saw seven cases of actively bleeding ulcers within ten days. In another hospital eleven cases of haemorrhage from ulcers were admitted during the same period. They suggest that this is an example of the Schwartzman phenomenon. This phenomenon is elicited by the injection of a bacterial filtrate locally into a tissue followed by the injection into the blood stream of another filtrate from eight to 120 hours later. The two filtrates are not specifically related to one another. The first injection produces a state of reactivity in the local tissue and the second or provocative injection produces lesions characteristic of the phenomenon at the

reactive site. The lesions are predominantly haemorrhagic and apparently due to marked capillary fragility. Whatever the primary cause of gastric ulcers may be secondary bacterial invaders are commonly found in the ulcer bed. This may be responsible for a state of reactivity in the tissues of the ulcer. Then viruses and bacterial infections in distant organs may be able to produce haemorrhagic and necrotic reactions in the ulcer by way of the general circulation. This theory would account for the alleged frequency of haemorrhage and perforation in the subjects of gastric ulcer following acute respiratory infections.

## Surgery

### 355 Tuberculous Tenosynovitis

F. PERRICONA (*Chir. Organi Mov.* January 1938 p 24) has seen forty cases of tuberculous tenosynovitis treated by various methods during the last thirty-six years. Tuberculous tenosynovitis is comparatively rare though tuberculosis is the most frequent cause of chronic disease of the tendon sheaths. It used to be nearly three times as frequent in men as in women at the beginning of this century but present day figures would seem to be nearly equal for both sexes. Occupation, heredity and trauma are possible factors in aetiology. The right hand and three times more commonly affected than the left and the flexor tendons are more usually involved than the extensors. The treatment of choice is excision of the whole of the affected sheath or sheaths. This means that the tendon is very likely to become involved in adhesions unless it is moved at the earliest possible moment—in fact without waiting for the wound to heal. If this immediate mobilization is properly carried out the prognosis is good recurrence is rare.

### 356 Squamous-celled Carcinoma of the Renal Pelvis

J. LAZARUS (*J. Urol.* January 1938 p 34) recorded a case of squamous-celled carcinoma originating in the pelvis of the kidney and invading the descending portion of the duodenum. The patient a man of 57 complained of pain in the right lumbar region with increased urinary frequency, haematuria, anorexia and loss of weight. For six years he had suffered from thrombo-angitis obliterans. Following radiography, cystoscopy and urography no diagnosis seemed to be either a right calcareous pyonephrosis or a duodenal ulcer. Operation was carried out and showed the right kidney to be greatly enlarged and adherent to the diaphragm above and below to the perirenal tissues and to the second portion of the duodenum. There was a large branching calculus in the renal pelvis. The upper two thirds of the kidney were pyonephrotic while the lower third was involved in a large fungating necrotic tumour about the size of a grapefruit which was intimately adherent to the second portion of the duodenum. The kidney was removed and the patient was discharged from hospital twelve days after operation. Shortly afterwards a swelling appeared over the posterior angle of the wound. This was opened and a quantity of thin turbid fluid was drained and a drainage tube being inserted. The discharge from the wound consisted of duodenal contents. The patient died eight days after the first operation. It is pointed out that a pre-operative diagnosis of squamous-celled carcinoma of the renal pelvis has never been made. Pain is a frequent symptom but there is no marked bleeding. This is of carcinoma as opposed to renal calculus or bacterial infection. The prognosis is poor, and there is no record

of even a five-year survival. Metastases have been reported in various organs, but the case described appears to be the first in which the duodenum was involved. Whenever possible nephrectomy should be carried out, the value of irradiation in the treatment of this type of growth is extremely doubtful.

357

**Carcinoma of the Penis**

G S FOULDS and B W STEVENS (*Brit J Urol* December, 1937, p 368) review a series of eleven cases of carcinoma of the penis. The relationship between phimosis with retained irritating secretions and the incidence of carcinoma is pointed out, circumcision in infancy appears to give complete protection. In only one of the cases reviewed had circumcision been carried out, and then only after the appearance of a small ulcer on the inner surface of the prepuce. Scars resulting from injury or ulceration may be the site of malignant change. Patients seek treatment because of the presence of a definite ulcer or swelling with sometimes a watery discharge from beneath the foreskin. Pain only occurs later, after extensive inflammation and ulceration have taken place. Four patients presented themselves with large fungating masses, and in one instance the corpora cavernosa were invaded. In seven cases in which the inguinal glands were removed there was no carcinomatous invasion, though all showed rather marked acute and subacute inflammatory changes. Diagnosis must rest on the microscopical examination of biopsy specimens. Venereal warts, tuberculous ulcers, chancres, and proctitis venerea must be regarded with suspicion when they are seen in men past middle life. Carcinoma of the penis is of the squamous type and usually occurs after prolonged chronic irritation. Its course is slow with late metastasis. Treatment depends on the size and type of lesion. A small ulcer of a low degree of malignancy may be destroyed by fulguration followed by treatment with radon seeds or a surface application of a radium element pack. Larger growths require amputation of the penis first followed by block dissection of the inguinal glands when necessary and after healing of the stump has taken place. Operation should be followed by deep x-ray therapy. Treatment by means of radium may be palliative in advanced cases when operation is not possible.

**Therapeutics**

358

**Serum Treatment of Pneumonia**

W D SUTLIFF (*Med Clin N Amer* January, 1938, p 19) stresses the importance of early diagnosis and of specific treatment in lobar pneumonia. He reports two cases illustrating the value of early serum treatment. In the first case type I pneumococci were isolated from the blood within a few hours of the onset of symptoms, and from the sputum twenty-four hours later. Specific serum was administered intravenously in the following doses within two days: 3,000 units, 17,000 units and four doses of 20,000 units. The temperature fell to normal on the third day of the disease. In the second case, type VII pneumococci were obtained from the sputum on the fourth day of illness. Type VII serum, 100,000 units, was given in divided doses over a period of six hours. The temperature fell to normal eight hours after the last dose. Symptoms are usually of more value than physical signs in making an early diagnosis of pneumonia, x-ray examination may help. Early identification of the causal organism and the use of appropriate serum are of supreme importance. Precautions are taken to prevent reactions due to serum sensitivity. A conjunctival test is made by dropping one or two drops of a 1 in 10 dilution of horse serum into the conjunctival sac. Injection of the vessels within twenty to thirty minutes indicates sensitivity. An

958 B

intradermal test with 0.1 c cm of 1 in 100 horse serum is also performed, a wheal and erythema in twenty to thirty minutes shows sensitivity. In these cases great caution must be observed. Doses of serum used by Sutcliffe are as follows: type I, 50,000 units in divided doses at two hour intervals; types II, V, VII, VIII, and XIV sera are given in amounts of 100,000 units in divided doses. When bacteraemia is present, when patients are over 60 years of age, in pregnancy or when more than one quarter of the total lung tissue is involved, the dosage is doubled.

359

**Trichlorethylene in Angina**

F A WILLIUS and T J DRY (*Amer Heart J* December 1937, p 659) report their results in the treatment of anginal syndromes by inhalations of trichlorethylene. Glass ampoules containing 1 c cm of the drug were broken in several layers of gauze and the vapour inhaled by the patient for exactly two minutes while in the recumbent position. This was done morning and evening for the first week, then twice daily on alternate days during the second week, and from then on twice daily for two days each week. Forty cases were treated. The results were rather disappointing. In eighteen cases varying degrees of improvement occurred, only one patient obtained complete relief, but the others had fewer attacks, which were less severe. In five cases there was temporary improvement, and in thirteen cases no improvement at all was noted. Four patients died during the course of treatment, two of them had been temporarily improved. The authors consider that this method should be given a trial when other measures have failed. According to them the drug is well tolerated, and its administration appears to be perfectly safe.

**Anaesthesia****360 Toxic Jaundice following Pentothal**

J M VALZEY (*Brit J Anaesth*, January 1938, p 55) reports the case of a female patient, aged 44, who had been under treatment for anaemia for nine years and had had an operation for haemorrhoids three years previously under nitrous oxide and ether anaesthesia preceded by omnopon-scopolamine, without ill effect. As the haemorrhage and anaemia continued, she was again admitted and two haemorrhoids were ligatured, she was given omnopon, grain 1/3, scopolamine, grain 1/150, followed by 6 c cm of 10 per cent pentothal sodium solution. The operation was without incident, but next day she was nauseated and the urine contained albumin. The following day jaundice appeared, and increased for ten days. The liver was palpable and tender, and the urine was bilirubin stained. She was treated with a high carbohydrate diet, calcium lactate by the mouth, and had 10 c cm of calcium gluconate injected intramuscularly on four occasions. She made a complete recovery.

361

**Epidural Anaesthesia**

P GRAFFAGNINO (*New Orleans med surg J* January, 1938, p 396) outlines the history of the method and the anatomy and physiology of the parts concerned, he has used this technique particularly in obstetrical and gynaecological cases. He makes his injection in the second lumbar space with the patient lying on her side, and uses a fine spinal needle with a glass fluid indicator attached, this shows a negative pressure when the epidural space is reached. A pause of five minutes after the first 10 c cm are injected eliminates the possibility of subdural injection. The solution commonly used is 50 c cm of 1 per cent novocain to which a small amount of pantocain is added, but without adrenaline or ephedrine. The onset of anaesthesia may be immediate or after as long as th

minutes, the duration is from half an hour to two hours. In 174 gynaecological operations of all classes the method gave 144 excellent results and thirty failures (17 per cent). On account of the difficulty and uncertainty of epidural as compared with spinal anaesthesia the author does not recommend it for routine gynaecological use. Seventy-seven obstetrical operations were also carried out including eleven Caesarean sections. In most cases the results were good but the method is not recommended for versions as the uterine contractions are unaffected. There may also be difficulty in timing the anaesthesia for delivery. Reactions requiring treatment occurred in only three cases.

### 362 Spinal Anaesthesia in China

Y. MING-TING (*Chin med J* January, 1938 p 37) tabulates and discusses the replies to a questionnaire upon the use of spinal anaesthesia in China during the years 1931 to 1935. Of the thirty-six hospitals approached only twelve replied but reports of a further 2,117 cases were obtained from the literature bringing the total up to 11,118 cases. Each year showed an increase in the number of spinal anaesthetics given the total for 1935 being more than double that for 1931. Partial or complete failure was reported in fifty-four cases or 0.5 per cent. Seven deaths occurred or 0.063 per cent of which six were from sudden collapse or heart failure on the operating table while one was from reactionary haemorrhage eleven hours later. In addition two patients died from intracranial haemorrhage after three and four weeks. The drug most often used was novocain in distilled water in strengths of 6 per cent (4,219 cases), 10 per cent (2,881 cases) and 5 per cent (1,000 cases). Stovaine has been largely given up as its administration is so often followed by post-operative retention as have spinocain on account of uncertainty of duration and percaine because of severe reactions, fever, headache and vomiting. A small series in which pantocain was used showed good results and long duration of anaesthesia. The author suggests that the maximum dose of novocain should be 0.2 gramme and that 0.15 gramme would be required for the average Chinese patient weighing about 120 lb. for a one-hour operation. He advocates injection by the usual technique in the fourth lumbar space followed by immediate Trendelenburg tilting of the table for safety. He considers that anaesthesia should not extend higher than midway between umbilicus and xiphisternum. As contraindications he suggests high or low blood pressure—that is, systolic above 170 or below 90 mm Hg—general or local sepsis, shock and mental conditions—for example epilepsy and hysteria.

### 363 Ether Convulsions

F. THIERRY (*Anesth et Analg* February 1938 p 55) induced ether anaesthesia with an Ombredanne mask in a female patient of 40 years to whom morphine and atropine had been given. To correct slow and shallow breathing carbon dioxide was being given when after five or six deep breaths a violent spasm of the upper limbs occurred. After removal of the mask this ceased and anaesthesia was continued without further carbon dioxide being administered. Much ether was used and relaxation was poor. In the discussion on this case many reports from English and American journals are quoted including that of Nosworthy's self-administration of carbon dioxide and the strange fact is brought out that in spite of the frequency of ether convulsions in other countries no case has been reported in France although the Ombredanne mask is commonly used with a high percentage of accumulated carbon dioxide. The activating cause in this case appears to have been a sudden change in acid-base equilibrium caused by the added carbon dioxide. The administration of the latter with this mask would appear undesirable. Predisposing causes are usually

present (pyrexia, sepsis etc. and possibly atropine). Treatment is by artificial respiration with perhaps intravenous barbiturates to control the convulsions. Oxygen and carbon dioxide mixtures should be used cautiously and gradually since sudden changes of carbon dioxide content in either direction may set up convulsions. Reports of animal investigations are quoted showing *inter alia* the stimulating effect of high ether concentrations on the motor centres also that a sudden return to fresh air may precipitate convulsions which are often fatal. The incidence and severity of such convulsions are increased by section of the vagus in the neck. Both atropine and ether increase the excitability of the motor cortex. Inhalation of ether has been shown to abolish the effect of hypnosis in some animals while amounts of ether otherwise ineffective were found to cause stimulation after a small dose of a hypnotic.

### 364 Obstetrical Analgesia with Rectidon

ENIMERT and GOLDSCHMIDT (*Strl med J La Grange* March 1938 p 240) have carried out 200 obstetrical analgesias with sodium amyl beta bromoethyl malonate known in America as sigmoidal and here as rectidon. The drug is supplied in 10 per cent solution ready for use and is injected direct into the rectum and as high as possible with a syringe and catheter. The rectum must be emptied by enemata and labour must be well established with dilatation of the cervix beginning. The initial dose is usually 10 ccm and gives analgesia for four to six hours after which further amounts of 5 ccm may be injected when labour is prolonged. The effect of the drug is shown in about fifteen minutes and reaches a maximum in two hours after which it decreases. The patient usually sleeps between her pains and responds to contractions with slight moaning etc. Excitement and restlessness are rare and occurred in only 4 per cent of cases. Some nervous patients were given 1.48 grain of diazepam one hour before the rectidon with good effect. Unusually deep sleep in two cases was successfully treated with coramine. Labour was not delayed and there was no increase of operative frequency. There was no maternal or foetal mortality and no increase of morbidity. Complete analgesia and amnesia was obtained in nearly 80 per cent of the cases.

## Obstetrics and Gynaecology

### 365 Intra-abdominal Radium for Cancer of the Cervix

F. DAELS (*Zbl Gynäk* February 26 1938 p 333) has previously sought to secure radium irradiation of the deeper cancerous zones in cases of carcinoma of the cervix by the following measures: complementary to radium applications to the cervix (1) radium drainage into the abdominal but extraperitoneal of the true pelvis by means of radium-containing tubes passed in various directions along the pelvic wall and (2) exteriorization of the pelvis in which the pelvis is marsupialized after transverse hypogastric incision before intrapelvic irradiation. He acknowledges the danger of phlebitis and inflammation which accompanies the first procedure and the technical difficulties and disadvantages of the second. He is now placing radium within the pelvis by using intra-abdominal incisions. The technique he says has not yet been perfected but his experience comprises thirty-six cases—two deaths within the first weeks of treatment from peritonitis and one from embolus. One intra-abdominal vesical fistula healing spontaneously. One case has been found safe to make the pelvic effusion more those to the primary growth. The intra-abdominal tubes are left in for about 10 to 15 days and the intrapelvic and intra-abdominal doses are 60 to 100 mg. A medium dose of 60 to 100 mg. is recommended.

incision 4 to 5 cm long serves for exploration of the pelvis and the introduction of two large curved silver, gold-coated, partially lead-lined tubes into the pouch of Douglas (one on each side) and two into the vesico-uterine fossa, their outer ends are brought out through and sutured near four small hypogastric stab-wounds. Small tubes containing radium are placed within the large tube at the distance which palpation of vessels and metastases shows to be desirable, each silver tube is provided externally with four narrower tubes of different lengths through which specimens of the fluid exudation can be withdrawn for bacteriological and cytological investigation.

366

**Anaemias of Pregnancy**

V FODERL (*Wien klin Woch* February 11, 1938, p 168) states that a pseudo anaemia occurs in 50 per cent of all pregnant women. The blood plasma is increased, the red blood corpuscles relatively decreased to 3 million per ccm, the haemoglobin is 60 per cent, the colour index below 1, no abnormal cells are found. No symptoms occur and thus no therapy is required. The condition disappears in the puerperium. True anaemias in pregnancy are rare, and only occur in 3 to 8 per cent of all cases. With hypochromic anaemia clinical symptoms are present, and the children are often anaemic. Treatment with large doses of iron is successful and the condition clears up at the end of lactation. Pernicious anaemia may be complicated by pregnancy or may arise during pregnancy. In the latter event the prognosis is grave, the mortality is 40 to 60 per cent. Blood transfusions are sometimes required when the administration of liver and iron fails. In favourable cases the anaemia disappears during the puerperium but recurs in succeeding pregnancies. Termination of the pregnancy is rarely indicated. Normocytic aplastic anaemia is very rare in pregnancy, the author describes a case in detail. It is due to a toxic disturbance of the haemopoietic system, the red and white cells are diminished and the colour index is below 1. No regenerative forms are found and there is no evidence of haemolysis in the blood or serum. The condition is uninfluenced by the administration of liver or iron but is amenable to blood transfusions.

**Pathology**

367

**First and Second Vaccinations**

O NORDLANDER (*Svenska LakSallsk Forh*, 1938, Supplement 12, 2, p 647) quotes figures from the Swedish Army Medical Service to show how much more frequent and prolonged are the serious reactions following the vaccination for the first time of young adults than are the reactions following the vaccination of young adults already vaccinated in childhood. In a three-year period beginning on October 1, 1934, there were 94,629 recruits who were either vaccinated or revaccinated. Only 996 represented first-time vaccinations, and among these men there were as many as 369 (37 per cent) whose reaction was so violent that it entailed interference with attendance to military duties, the average duration of invalidism being five days. Among the 93,633 recruits who had been vaccinated in childhood and were now vaccinated for the second time there were only 3,355 (3.6 per cent) who reacted so violently that they were reported sick, the average duration of invalidism was four days. The fact that only about 1 per cent of the recruits in the period under review had not already been vaccinated in childhood must be traced to the strictness of the vaccination legislation hitherto enforced in Sweden. With the possibility before him of this legislation being modified so as to make vaccination more or less voluntary the author calculates what will be the vaccination sickness rates some

years hence, when approximately every other recruit vaccinated represents a first-time vaccination. There will then be nearly 6,000 recruits ill for five days each every year, a sickness rate more than six times as great as that existing at the present time so far as vaccination in the army is concerned.

368

**Alcohol Test of Hepatic Function**

E SERIANNI and G LOLLI (*Dtsch med Wschr* February 18, 1938, p 258) report from the University Institute for Human Physiology in Rome their experiences with a new test of hepatic function. It depends on the fact that, while in health the curve representing the concentration of alcohol in the blood varies greatly according to whether the alcohol is taken on a fasting or a full stomach, in certain diseases of the liver this curve is the same whether the alcohol be taken on a full or fasting stomach. The liver conditions which give rise to this abnormal reaction are Laennec's cirrhosis, new growths of the pancreas, compression of the biliary passages with jaundice, and certain forms of cholecystitis with or without gall-stones. The test consists in giving by the mouth 0.5 ccm of alcohol for every kilogramme of body weight in a 20 per cent watery solution. The blood is tested for alcohol five minutes later, the test being repeated every ten minutes during the first hour, and every fifteen minutes during the second and third hours. A day or two after these tests have been carried out in the fasting state the same procedure is followed an hour or two after an ordinary mixed meal has been taken. In health the blood-alcohol curve will be higher and longer after alcohol has been taken in the fasting state than after a full meal, whereas in the presence of the above-mentioned diseases of the liver the behaviour of both the full and the fasting curves will be identical.

**369 Bone-marrow in Pulmonary Tuberculosis**

G LANZA (*Riv Patol Clin Tuberc* January 31, 1938, p 1) has carried out investigations on the bone marrow in forty cases of tuberculosis. The samples were obtained by sternal puncture. He states that in all advanced cases the marrow shows both qualitative and quantitative changes. The qualitative changes are mainly the following: (1) anomalies of maturation both of the leucopoietic and the erythropoietic elements, particularly the frequent discrepancy between the degree of maturity of the nucleus and of the protoplasm, (2) poikilocytosis and anisocytosis, (3) degenerative changes, particularly in the granulocytes with "toxic" changes in the granules, vacuole formation, and, rarely, fatty degeneration. The quantitative changes include (1) a reduction in the number of differentiated and less mature elements in both red and white cells, (2) relative excess of the more mature elements of both series, (3) a marked reduction in the platelet-forming elements and an increase in the number of plasma cells, (4) changes in the leuco-erythrocytic ratio (more often to the advantage of the red series) and in the maturation-curves in both series. A comparative study of the above factors shows that the bone marrow is in a state of hyperactivity in 95 per cent of cases, 32.5 per cent of these 40 per cent show increased activity, 32.5 per cent show a reaction of an anaemic hyperplastic type, and 22.5 per cent an "infective" type of reaction—that is, a predominantly leucogenetic reaction, in two cases only (5 per cent) was there any deficiency in the erythropoietic function of the marrow, in contrast with the findings in the peripheral blood, this would appear to hold good even in cases of severe anaemia. The author thinks these changes may be related on the one hand with the increased requirements of red or white cells in the peripheral circulation, and on the other hand with local stimuli—for example, the "myelo-toxic factor" shown by the presence of degenerative elements, especially in the white cells.

# MENFORMON TABLETS

to reverse  
menopausal changes

' Finally there is one important observation that I would bring to your notice. Patients treated with oestrin for whatever complaint, frequently volunteer the information that they experience a sense of well-being. All of us suffer only too frequently from the voluble and discontented menopausal patient with all her aches and pains and I have been gratified by the CHANGE OF MENTAL ATTITUDE which oestrin has afforded to some of the patients converting them almost into cheerful kindly rays of sunshine.

# 1937 AT THE CLINIC

## 3,902 PATIENTS

(236 members of the Medical Profession  
or their dependents)

## 3,004 operations in the eight operating theatres

## OVER £5,000 SPENT ON RENOVATIONS & IMPROVEMENTS

**T**ODAY The Clinic, the wonderful Nursing Home in Devonshire Place, W 1, might have been richer by over twelve thousand pounds compared with two years ago—to such an extent have the public and the Medical Profession responded to its offer of the finest possible Nursing Home Service

Yet actually it is the Public and the Medical Profession who are the richer—for the whole of that sum (more than £12 000) has, true to the principles embodied in the Constitution of the operating Company, been put

back into The Clinic and spent on renewals and improvements of equipment and services, and thus without any increase of charges to the public

A large proportion of the money was spent in a thorough reorganisation of the nursing and catering services, previously at a remarkably high standard. As to catering at The Clinic now "It seems, nowadays, you have to be ill," wrote a patient there recently, "to learn how to live really well"

While the average charge for a room at The Clinic remains at fourteen guineas, charges actually range, as before, from 10 to 18 guineas, while there are a few suites at 25 to 42 guineas. All these rates include a free dispensary service—in "extra" which cost The Clinic nearly £2,400 last year. Enquiries and visits from the medical profession are welcomed, and the Secretary will be glad to furnish further details

## MIDDLESBROUGH EDUCATION COMMITTEE

### APPOINTMENT OF ASSISTANT SCHOOL MEDICAL OFFICER

Applications are invited from duly qualified candidates who are not over 45 years of age for a position as ASSISTANT SCHOOL MEDICAL OFFICER to act under the School Medical Officer in connection with the medical inspection and treatment of school children and such other duties as may be required by the Education Committee.

Commencing salary £500 per annum (provided the successful candidate has had not less than three years postgraduate experience) rising by annual increments of £25 to £700 per annum. The Committee may at their discretion take into account previous experience as an Assistant School Medical Officer in determining the amount of the commencing salary. The successful candidate will be required to devote his (her) whole time to the duties of the office. The appointment will be subject to the provisions of the Local Government and Officers Superannuation Act 1922 and the salary of the candidate will be required to pass a written examination. The appointment will be for a term of two calendar months.

Applications may be obtained on application to the Director of Education, Education Committee, Middlesbrough, to whom they should be sent not later than May 15th 1938. Candidates should send their names on a postcard to the Secretary, Middlesbrough Education Committee, 10, Victoria Road, Middlesbrough, to whom they should be sent not later than May 15th 1938.

PRESTON KITCHEN

## CHARLES MURCHISON SCHOLARSHIP IN CLINICAL MEDICINE

The next EXAMINATION for this SCHOLARSHIP will be held at the ROYAL COLLEGE OF PHYSICIANS OF LONDON ON TUESDAY JUNE 14th 1938 and following days.

The Examination is open to any Student of Medicine whether holding a Medical qualification or not who subsequently to the date of passing his professional Examination in Anatomy and Physiology for a Medical qualification commenced clinical studies not less than two and a half and not more than five years previously at a Medical School in London recognized by the Royal College of Physicians or at the University of Edinburgh in eluding Medical Classes recognized by the Medical Faculty of the University.

The Scholarship is of the value of Twenty Guineas and is tenable for one year.

Intending Candidates are required to send in their names to the Registrar of the Royal College of Physicians Pall Mall East London SW 1 not later than May 31st with evidence of the duration of their Medical Studies from the Deans of their respective Schools and evidence of the date at which they passed their examination in Anatomy and Physiology.

(The Examination for 1939 will be held in the University of Edinburgh.)

CHARLES NEWMAN M.D.

Assistant Registrar

Pall Mall East SW 1

## CHILD GUIDANCE COUNCIL

### FELLOWSHIPS IN PSYCHIATRY

The Child Guidance Council offers THREE FELLOWSHIPS each of £300 tenable for a year for half time work at the London Child Guidance Clinic 1 Canonbury Place Islington N.1.

Candidates should hold the Diploma in Psychological Medicine or show evidence of psychiatric knowledge up to a similar standard. Experience in Pediatrics or School Medical service will be regarded as an asset.

The Fellows will be expected to commence work in October this year.

Further particulars and forms of application may be obtained from the Secretary Child Guidance Council 1 Woburn House Upper Woburn Place London W.C.1.

Applications should reach the Secretary not later than May 10th 1938 and should be accompanied by copies of three recent testimonials.

## BRITISH ASSOCIATION OF RADIOLOGISTS (FELLOWSHIP BOARD)

### FELLOWSHIP EXAMINATION

The second Examination for the Fellowship of the Association will be held in London during the period November 28th to December 2nd 1938.

The Examination is limited to Medical Practitioners who are duly registered in the country in which they practise and who have held a recognized Diploma in Radiology for not less than two years. The Diplomas so far recognized are those granted by the following bodies: the Universities of Cambridge, Edinburgh, Liverpool, and London; the Conjoint Board of the Royal College of Physicians of London and the Royal College of Surgeons of England; and the American Board of Radiology.

The principal subjects of the Examination are

### I. RADIO DIAGNOSIS II. RADIOTHERAPEUTICS

Every candidate must pass on an honourable standard the examination in either Radiodiagnosis or Radiotherapeutics. A candidate may if he chooses elect to take honours in both subjects. All candidates will also be examined in General Medicine, General Surgery and General Pathology but those who have passed examinations for higher medical or surgical qualifications may be exempted partly or wholly from this part of the Fellowship Examination. A thesis (or published work in lieu of a thesis) concerned with some aspect of the honours subject is also required from candidates. This thesis may be lodged with the Warden at any time after the expiration of two years from the taking of a radiological diploma.

In addition to passing the Examination candidates must comply with the conditions for ordinary membership of the Association before they can be elected Fellows.

Practitioners intending to specialise in Radio are invited to register their names with the Board in order that they may receive information.

Entrance forms which must be sent in before the end of August 1938 and further particulars may be obtained from

F. HERNAMAN JOHNSON M.D. D.M.R.E.  
Warden Fellowship Board  
British Association of Radiologists

## SEAMENS HOSPITAL SOCIETY

The Committee of Management invite applications for the appointment of PHYSICIAN in charge of out patients at the Dreadnought Hospital Greenwich. The elected candidate will have charge of the out patients and will be appointed for 12 months but will be eligible for re-election.

Candidates must be Doctors of the Royal College of Medicine of a University in the United Kingdom and Fellows or Members of the Royal College of Physicians of London.

Applications to be sent in on or before Friday May 27th to the undersigned from whom further particulars can be obtained. The successful Physician is a candidate for the Fellowship of the Society.  
Greenwich April 25th 1938 F. A. HODGKINSON Secretary

# ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in July, 1938

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty

At the end of three years' service, officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000

At the end of five years' Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax)

Full opportunities exist for transfer to the permanent list, and periods of unemployed or half pay are very rare. The assistance of private income is not necessary for the purpose of supplementing official pay and allowances

Opportunities are available for officers on the permanent list for post graduate study, to specialise, to take higher examinations and to obtain further qualifications

Naval Medical Officers are included in the Scheme for Marriage Allowance under the same conditions as for other Naval Officers

Copies of the regulations for entry and conditions of Service, including rates of pay, allowances and retired pay may be obtained from the Medical Director General of the Navy, Admiralty, S.W. 1, and from the Deans of all Medical Schools

Applications for entry from intending candidates must be received not later than 31st May, 1938

## CITY OF PORTSMOUTH

### ASSISTANT MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER (Male)

Applications are invited from medical men not over 40 years of age for the above appointment. The maximum salary will be £60 per annum. The commencing salary will not be less than £40 per annum and will be fixed according to the qualifications and experience of the successful applicant, and will rise by increments of £5 to £60 per annum.

The duties are concerned chiefly with the medical inspection and treatment of school children and preference will therefore be given to candidates with experience of School Medical work and of diseases of children.

The appointment will also include duties in the Health Department and it is accordingly desirable but not essential that applicants should hold the D.P.H. or a similar Public Health qualification.

Forms of application may be obtained from the Chief Clerk Education Offices Guildhall Portsmouth, and should be returned accompanied by three testimonials of recent date not later than May 16th 1938 to the undersigned.

The Guildhall F. J. SPARKS  
Portsmouth Town Clerk.  
-April and 1938

Town Clerk

Guildhall Nottingham  
April 22nd 1938

## UNIVERSITY OF ABERDEEN

The Senate will award A. W. GARDEN FELLOWSHIPS in June 1939 for the period commencing October 1st 1939. The FELLOWSHIPS are of the annual value of not less than £200 and are normally tenable for from 3 to 5 years in any of the Departments of the Faculty of Medicine in the University of Aberdeen. Graduates of Medicine of any British University are eligible, but preference will be given to Medical Graduates of the University of Aberdeen with suitable qualification.

Applications must be received before May 1st 1939 with the Secretary of the University of Aberdeen, Marischal College, Aberdeen from whom particulars may be obtained.

## CAERNARVONSHIRE COUNTY COUNCIL

## ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER

Applications are invited for the above post from Registered Medical Practitioners of not more than 40 years of age at a salary of £60 per annum rising by annual increments of £5 to £70 per annum plus a travelling allowance in accordance with the scale adopted by the Council.

Candidates must, subsequent to qualification, have had at least three years' experience in the practice of the profession and also have had special experience in Maternity and Child Welfare Work and the School Medical Services. Practical experience in Immunization Method is also desirable. The possession of a Diploma in Public Health or an equivalent qualification is essential.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act 1928, and the successful applicant will be required to pass a medical examination.

Canvassing either directly or indirectly will be a disqualification.

A knowledge of Welsh is essential. Further particulars about the post may be obtained from the County Medical Officer of Health, County Offices, Caernarvon.

Forms of application may be obtained from the undersigned to whom they should be returned completed together with copies of three recent testimonials, and endorsed "Medical Officer" by not later than Monday, May 16th 1938.

Dated this 5th day of April 1938  
DAVID G. JONES  
of the County Offices, Caernarvon  
Clerk of the County Council

## BOROUGH OF HENDON

## ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER (MALE)

The Hendon Borough Council invite applications for the above post.

Applicants must be fully qualified Medical Practitioners and hold a Diploma in Public Health or an equivalent qualification.

The duties will be mainly in connexion with the Council's Maternity and Child Welfare and School Medical Services, but in addition other duties under the direction of the Medical Officer of Health.

The salary is £600 per annum, rising by annual increments of £5 to a maximum of £700 with a car allowance of £20 per annum if the successful candidate provides his own car for use in connexion with his duties.

The appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act 1928 and the successful candidate will be required to pass a medical examination.

Applications on forms to be obtained from the undersigned together with copies of not more than three recent testimonials to be sent to the undersigned not later than the first post on Thursday, May 5th 1938.

Canvassing directly or indirectly will be deemed a disqualification.

Dated this 1st day of April 1938

# KENT COUNTY COUNCIL

## PUBLIC HEALTH DEPARTMENT

### CONSULTANT OBSTETRICIANS

The County Council invites applications from registered medical practitioners adequately qualified and experienced in obstetrical work for four part-time appointments as Consultants in Maternity and Gynaecology. The private practitioners require the assistance of a Consultant in Maternity and Gynaecology. One consultant will be appointed for each of the County Maternity and Child Welfare Areas: (a) Chatham, Gillingham, and Rochester; (b) Tunbridge Wells; (c) Ashford; and (d) Canterbury. Each of the consultants appointed will be required to reside in or near the town to which his or her area is added and to appoint a deputy who must be approved by the County Council to act in his or her absence. Consultants will be arranged by medical practitioners but the consultants will be required to submit reports of cases to the County Medical Officer and comply with such other requirements as may be specified from time to time by him.

The remuneration of the consultants will be as follows:—Consultants at or within one mile of the town £1,500; up to 5 miles £1,000; from 5 to 10 miles £750; over 10 miles £500. The appointments will be at the pleasure of the County Council. The arrangements will be reviewed at the end of the first year.

Forms of application and if required further detail of the appointments can be obtained from the County Medical Officer, Sessions House, Maidstone, to whom completed application forms should be returned not later than May 15, 1938.

W. L. PLATT

Clerk of the County Council

AUTHORS AND TITLES	DETAILS	COMMENTS
<b>COWARD</b> BIOLOGICAL STANDARDISATION OF THE VITAMINS	By KATHARINE H COWARD D.Sc. Pp viii + 228 +4 figures 29 tables 12s 6d	Nothing is omitted which could enhance the usefulness of this work. Dr Coward has given us a unique and indispensable book. Others have written on the biological estimation of the vitamins but no one else has attempted to expound the underlying principles of biological standardisation. <i>The Lancet</i>
<b>BARNHILL</b> SURGICAL ANATOMY OF THE HEAD AND NECK	Pp xvi + 922 with 431 illustrations many in colours. 90s	This is a most extraordinary and exhaustive study of the subject and will be of great practical value to all interested in the surgery of these intricate regions. The book has been designed especially for the use of otolaryngologists, ophthalmologists and oral and general surgeons and is very fully illustrated.
<b>GASK &amp; ROSS</b> SYMPATHETIC NERVOUS SYSTEM	SECOND EDN. Pp xii + 186 with 49 illustrations including 15 plates 16s	Without doubt this is the most practical and quite the most useful book on this subject that has so far been published. It is not often that a book appears which has such a distinct appeal not only to the student and surgeon but also to the general practitioner. <i>Medical Press and Comment</i>
<b>FORD</b> DISEASES OF THE NERVOUS SYSTEM IN CHILDHOOD	By Prof. F. R. FORD M.D. Pp xiv + 924 with 107 illustrations 38s	This work is exceedingly comprehensive and it must prove most valuable to all neurologist, paediatricians and orthopaedists. To the end and all other medical men interested in children it can be most warmly recommended. Charts, tables, illustrations and case histories illuminate the systematic descriptions of the many different conditions. <i>B.M.J.</i>
<b>BANNEN</b> THE RADIOLOGY OF PULMONARY TUBERCULOSIS	By J. E. BANNEN M.B. Ch.B. D.M.R.E. Pp viii + 156 with 9 plates 12s 6d	Practitioners will find this book extremely useful for it gives an excellent account of chest radiography. It avoids technicalities so that the volume appeals to the practising physician. The large number of radiograms which it contains adds greatly to its value. <i>Medical World</i>
<b>RUSSELL</b> OCCUPATIONAL TREATMENT OF MENTAL ILLNESS	Pp xiv + 228 with 41 illustrations including 6 plates 6s	The first book in England wholly devoted to this subject. Deals with the principles of occupational therapy and with methods of organisation and applying it through crafts and other activities. Invaluable to all concerned with the welfare of the mental patient and all others cut off from normal work.
<b>ALEXANDER</b> COLLAPSE THERAPY OF PULMONARY TUBERCULOSIS	Pp xvi + 706 with 567 figures showing 679 illustrations. 67s 6d	We have here the latest pronouncement and the most complete in any language. For many years this volume will be the <i>requis</i> <i>lira</i> book of reference. The practitioner interested in tuberculosis cannot afford to be without it as the most authoritative book in the English language. <i>Sanitary Medical Journal</i>

G.W.R. Travel Facilities for the Conveyance  
of Invalids

The Great Western Railway Company offer excellent facilities for the conveyance of hospital patients and other invalids.

Patients can make a throughout journey on the Company's new type of stretcher, which very materially adds to the comfort of invalids who have to travel lying down.

The Company also have well-appointed invalid saloons fitted with special couches suspended between the roof and floor to prevent oscillation, bedding being provided where necessary. The invalid saloons also contain arm chairs, settees, and table.

Meals are obtainable in most cases, invalid chairs are available, and every assistance is rendered by the Company's staff.

Full details of these facilities may be obtained from the Superintendent of the Line, G.W.R. Paddington Station or from any G.W.R. Station Master.

# The Modern Shorts for the sedentary man

The new, close-fitting Linia Shorts are a boon to the man leading a sedentary life. Made of elastic knicot, they exert a gentle beneficial massage on the abdominal area and give firm support. They are designed for men instead of ordinary under pants and are light, easily laundered, porous and hygienic.

A development of Linia Shorts is Linia Reinforced Shorts which have a panel of finer elastic over the abdomen for better support and control where there is a tendency to obesity.

## You can order by post

Perfect fitting guaranteed or money refunded. We make a reduction of 2s in the £ on purchases for personal use to members of the Medical Profession.

May we send you a fully explanatory booklet?

# DESOUTTER

## CASE RECORDS

### Case No H2354/1673 1936

The patient was suffering from muscular hypertrophy of the right leg, the circumference of the calf being twice, and the ankle nearly three times, that of the sound limb. The foot was deformed, necessitating a special shoe, and the patient's walk was most ungainly (Fig 1).

At the request of the surgeon, Mr Desoutter examined the patient in hospital before amputation to give his opinion as to —

- 1 *The best site of amputation in view of the peculiar difficulties of the case*
- 2 *The prognosis from the points of view of appearance and ability to walk well with an artificial limb*

It was decided to amputate 7" below the knee joint and to remove the hypertrophied muscle on the inner side of the leg. Figure 2 shows the great success with which the operation was performed. The scar on the inner side of the leg, extending from the end of the stump to just under the knee, seemed at first to need special attention, but by very careful

fitting of the artificial limb serious trouble was avoided.

Careful physical re-education played a large part in the success of this case, and the patient now walks very well and has a natural appearance.

# WHEN EVERYTHING ELSE HAS FAILED then try SHORT-WAVE THERAPY with SIEMENS ULTRATHERM

Suppose you are treating a purulent condition of antrum and sinuses

Such conditions are very well suited for short-wave treatment. Acute and septic cases react almost immediately, and even in those chronic cases where permanent healing cannot always be obtained one can, at least, promise freedom from symptoms for a long time

# AMPLIVOX HOUSE

## The New Home of the HIGH FIDELITY HEARING AID

Amplivox House accommodates an organization which in three years has become the world's largest manufacturer of High Fidelity Hearing Aids. This success has been achieved solely through the recommendations of medical men and enthusiastic users. Here is definite proof that sufferers from deafness are now fully alive to the vital importance of using high grade instruments and are putting performance first in purchasing a hearing aid. At Amplivox House they can compare all types of hearing aids with the many Amplivox models. They can avail themselves of the unique facilities offered by an organization which concentrates all its energies on the production of hearing aids for use individually and in churches, schools, theatres etc., and the development of special acoustic apparatus for the medical profession. Details of the full range of Amplivox aids should be in the hands of every Medical Practitioner.

## Efficient and Effective Support

### SCIENTIFICALLY Applied

The secret of the success of the Curtis Abdominal Support No 1 lies in its scientific application of power. At all times it gives even anterior-posterior pressure without undue constriction of the lower abdomen. The resulting support obtained allows for greater freedom and comfort than ever before. Medical men prescribe the Curtis Model No 1 for all forms of abdominal ptosis—viscerop-tosis, enteroptosis and gastrop-tosis, and it is also recommended for support of ventral hernia and scar tissue in the lower abdomen.

## MANDECAL

(Compound Calcium Mandelate B D H)

Clinical trials with Mandecal (*Lancet*, February 26th, 1938, p 494) on a series of 33 hospital patients have established the value of this product as a bacteriostatic and bactericidal agent in the treatment of urinary infections. Mandecal is also shown to be markedly less irritating and nauseating than the salts of mandelic acid hitherto used.

Further, in Mandecal the immiscibility of calcium mandelate has been entirely overcome, and it approximates to the ideal urinary antiseptic, it is particularly indicated for hypersensitive patients who may be unduly nauseated by other mandelic acid preparations.

# Prescribing with Confidence

The advantages of Rhinitol in the treatment of

## COLDS

### NASAL CONGESTION and CATARRH

and all other affections of the upper respiratory tract are —

- 1 Its very low ephedrine content.
- 2 Its property of emulsifying with body fluids owing to the vasogen vehicle.
- 3 Its complete freedom from irritant or toxic effects
- 4 Its rapid yet prolonged action.

T PEARSON & CO LTD MITCHAM SURREY

# ANTISEPSIS

The full development of Antisepsis demands an agent which while efficient, does not damage human tissues nor inhibit the normal function of the natural defences against infection. That Verpine is efficient has been proved during years of clinical trial. When used at fully antiseptic strengths Verpine has negligible effect on human tissues while one of its active principles encourages natural resistance to infection by promoting leucocytosis and is a protoplasmic stimulant. Verpine moreover, is agreeable to use and possesses a pleasant, refreshing odour.

# MILTON

Detergent, Penetrative, Germicidal, OSMOTIC, NON-TOXIC,  
Liquefactive, Regenerative

## OSMOTIC & NON-TOXIC

Like all hypertonic salines, Milton acts osmotically, promoting leucocytosis and reducing œdema

It is bland to living tissue and contains no caustic element 50% Milton applied to delicate cutaneous tissues for one hour was shown to have no irritant effect

Tests show that, compared with the standard preparation of its class (Dakin's Solution), Milton is decidedly non-irritating, also that its toxic effect upon growing tissue is unusually low, which may be taken as a very favourable indication

as regards the effect of Milton upon the repair of injured tissues

Laboratory researches have clearly demonstrated the qualities of this carefully designed preparation and its superiority over other "hypochlorite" antiseptics

Reports of these researches and a sample of Milton will be forwarded to any medical practitioner on request.

Milton is supplied at a standard strength ready for immediate use, and is stable. It is safe for either external or internal application

### The Ideal Spring Tonic

Livogen provides the ideal spring tonic for use in those varying conditions of lowered vitality which are so widespread at the end of the winter and in the early days of spring. These conditions, manifested in asthenia, lassitude, lethargy and debility, are often extremely difficult of exact diagnosis, but physicians everywhere report that the administration of Livogen is followed by a restoration of energy, increased appetite and a general return to normal conditions.

WHOLESALE AND  
EXPORT DEPARTMENT

★ *Extract from the British  
Medical Journal, 1936, 1, 954*  
**Idiopathic and Secondary  
Hypochromic Anæmia**  
"Ferrous chloride is the most  
efficient, probably because it is  
the form into which most of the  
available iron is converted in the  
stomach before absorption. A  
total daily dose of 9 to 18 grains  
of stabilized ferrous chloride  
(Boots), made up into capsules  
of 3 grains each (that is, one to  
two capsules thrice daily after  
meals), is sufficient for the most  
severe degrees of hypochromic  
anæmia. In this form it maintains  
its ferrous condition very well."

**BOOTS PURE DRUG CO. LTD. NOTTINGHAM, ENGLAND.**

## WHOOPIING COUGH

Detoxicated Whooping Cough Vaccine (Genatosan) has proved remarkably successful. Reports received from medical practitioners state that it usually reduces the frequency of the paroxysms after the first injection, and subsequent injections almost invariably clear up the condition. Owing to the elimination of the toxic elements of the germ during the process of manufacture, this vaccine may be given to infants and young children, in doses sufficiently large to produce the desired therapeutic effect, with an absence of harmful reaction.

The following is typical of many reports received from physicians —

*"I have been making a somewhat extensive use of your Detoxicated Vaccine for Whooping Cough, and am pleased to say that the results have been almost invariably gratifying. In nearly all my cases the very distressing symptoms have disappeared after the third injection."* M D

Additional information regarding this Vaccine will gladly be supplied on request

# OVALTINE

**FOR THE OLD AND FEEBLE**

**D**URING old age when the digestive powers and vitality are on the wane the problem of satisfactory feeding often becomes acute. A solution to this difficulty is found in Ovaltine. Its delightful flavour appeals to the jaded palate its digestive action aids the enfeebled assimilation while its high nutritive value stimulates the flagging metabolism. It is a boon to the aged.

In Ovaltine the nutritive constituents of fresh milk, eggs and malt are transformed into crisp granules which dissolve readily in milk to form a delicious beverage. A cup of Ovaltine in the morning ensures energy for the day and a cup on retiring generally relieves the sleeplessness so common a symptom of old age and gives digestive rest.

Ovaltine enriches the diet in certain important factors notably calcium and vitamins A and B, which recent investigations have shown to promote longevity.

Biliary extract	0.10
Lactic ferments	0.05 "
Agar-agar	0.05 ,
Fiat tablet	0.35

Initial Daily Dose  
Two Tablets

*Laxatives*, it is well known nowadays, must have two essential characteristics:

- 1 They must be biological i.e. they must accord with and imitate in their action the natural physiological processes of the intestine.
- 2 They must be capable of educating the intestine so that the habit of a laxative is not formed and the intestine can function unaided when bowel adjustment is attained.

*Taxol* has both these advantages.

*Taxol* has not the violent irritant action of many laxatives and purgatives but stimulates the intestine by processes which resemble those of nature. The intestinal gland which is an important part of its composition acts on the intestine by reinforcing the deficient function which has culminated in constipation. This stimulating action is gentle and does not force the weakened intestine to efforts beyond its power which would culminate in aggravation of the constipation.

*Taxol* is not habit forming. It re-educates the intestine to resumption of normal function unaided thanks to the biological nature of its action. It contains no irritant drug of violent and artificial action to which the intestine can become accustomed. On the contrary, many stubborn cases of constipation after a course of TAXOL revert to normal and regular peristalsis.

## Vitamin Concentrate or Natural Food?

The normal daily dosage of Bemax, i.e.,  $\frac{1}{2}$ -ounce, provides 200 International units of Vitamin B<sub>1</sub>, which is from four to ten times as much as the recommended daily dosage of certain Vitamin B<sub>1</sub> "concentrates" advertised to the medical profession. If a higher intake is required, it is possible to supply as much as 600 to 800 units of Vitamin B<sub>1</sub> daily by the administration of three to four tablespoonfuls of Bemax, and this in an entirely natural form at only a fraction of the cost of concentrates.

The Vitamin B<sub>1</sub> potency of Bemax is assured by biological assay of every day's output, and is from 12-15 International Units per gramme, about 400 units per ounce.

# BEMAX

A unique natural source of accessory nutritional factors

Vitamin B <sub>1</sub> —400 International Units per ounce	Vitamin E—the richest natural source 1.30 mg. per ounce

## THE LESSON OF ANTISEPTICS

LISTER'S discovery that suppuration of wounds was caused by bacterial infection and could be prevented by the use of antiseptics opened the way to the marvels of modern surgery. To-day, it is taken for granted that every operation will be carried out without the introduction of micro-organisms into the blood.

Recognition of the importance of germ-free cleanliness, however, is no longer confined to the operating theatre and surgery, it receives ever-increasing attention from the lay public. Health standards to-day

are higher than they have ever been, as a result. Naturally, elaborate precautions against infection are impracticable in everyday life, but fortunately adequate protection is provided by the liberal use of soap and water—provided that the soap is pure and has antiseptic qualities.

Wright's Coal Tar Soap has enjoyed the confidence of the medical profession for over 70 years. Leading bacteriologists advocate its use for everyday protection against infection, and it has been found that more doctors use Wright's than any other brand of toilet soap. Wright's has substantial antiseptic and antipruritic qualities, and is the only soap to contain

'liquor carbonis detergens' (Wright's), the valuable skin therapeutic used and recommended by the foremost dermatologists. You can use and recommend Wright's Coal Tar Soap with every confidence.

# CRUNCHY FOODS AND THE TEETH

---

Crisp, fibrous foods are generally considered to perform a useful function in scouring the teeth, thus keeping them free from sticky food particles, which are apt to ferment and cause decay. The plentiful saliva, which hard, dry foods produce, is also of value in cleaning the mouth.

Furthermore the vigorous mastication that hard foods demand is generally held to assist the growth and correct development of the jaws.

For these reasons many practitioners recommend that the normal diet should include a proportion of hard, dry foods. They find that Ryvita eaten daily has a beneficial effect upon the teeth, especially those of children. Free samples of Ryvita for distribution to patients will gladly be supplied on request.

*Relieves Nasal Congestion — Combats Infection*

Metaphedrin Inhalant No 99 (Abbott) contains the powerful antiseptic Metaphen 1 part in 2,500 and Ephedrine alkaloid 0.95% in a light bland mineral oil. • Metaphen has been found to be 250 to 1,500 times more germicidal than phenol, depending upon the organism tested. In 1:2,500 dilution it is non-toxic, non-irritating to mucous surfaces and does not coagulate serum or tissue albumins. The chief value of Ephedrine lies in its power to decongest and shrink the nasal mucous membrane. This is accomplished with little or no irritation. • This combination of antiseptic and

shrinking actions makes Metaphedrin Inhalant No 99 an especially useful agent for the treatment of hypertrophic rhinitis, coryza, nasal and sinus infections, and the nasal congestion of hay fever. The product is of great value as a preventive of infection and is frequently used at the onset of certain cases to cut short the course of the disease itself. It is also valuable for instillation into infected sinuses and for use in all rhinological operative procedures. • Metaphedrin Inhalant No 99 may be applied

topically or it may be prescribed as a spray. It is obtainable through pharmacies and is issued in ½-ounce, 1-ounce, 4-ounce and 16-ounce bottles. Enquiries for a free trial sample of Metaphedrin Inhalant No 99 (Abbott) and for professional literature are welcomed. The coupon below is for your convenience.

## THE CLINICAL BEARINGS OF THE PARATHYROIDS

By

W J E JESSOP, M D, M Sc, D P H

*Professor of Physiology, Royal College of Surgeons in Ireland*

In this paper I propose to deal with the general principles underlying the action of the parathyroid glands illustrating their clinical importance by such items as have fallen within my experience. Those who desire more detailed information are referred to one of the many reviews published on this subject of which the most recent by Hunter (1937) might be specially mentioned.

The parathyroids are small glands usually four in number, situated at the postero lateral margins of the thyroid. Occasionally one or more additional glands may be found either similarly situated or placed above or below the thyroid—even in a few instances within the superior mediastinum. The maximum total weight is less than 0.5 gramme. Histologically they consist of closely packed cells of two main types—principal cells with a faintly basophil protoplasm and eosinophil cells. We have no evidence to indicate definitely the relative importance of these types.

### The Parathyroid Hormone

The glands produce a hormone which has been extracted by Collip in a form suitable for intravenous injection but which has not yet been prepared pure enough for its chemical constitution to be determined and hence no synthetic preparation of it has been possible. For clinical purposes several commercial extracts of recognized activity are available though doubts are sometimes expressed regarding the uniformity of their potency. At present a unit is defined as one hundredth part of the amount necessary to raise the blood calcium of a dog weighing 20 kg by 1 mg per 100 ccm. The hormone is useless when taken by mouth.

Although it is generally agreed that the parathyroids are primarily concerned with regulation of calcium and phosphorus metabolism and that the various other manifestations of increased or decreased activity are only secondary to this function the precise mechanism by which the hormone acts has not yet been fully worked out. Several theories have been put forward suggesting that the primary influence is exerted on one or other of the calcium fractions and even on phosphorus metabolism.

From the point of view of the clinician it will suffice to state clearly what appears to be the most likely sequence of events. The activity of the parathyroid is normally governed by the level of serum calcium probably the ionized fraction. A fall in value of ionized calcium acts as a stimulus to secretion which may operate either directly or indirectly, if indirectly then either through a nervous mechanism or by stimulating the pro-

duction of a parathypotropic hormone by the pituitary. The primary object of this increased secretion is to raise the level of serum calcium to its normal level. Calcium is essential for proper functioning of the greater part of the neuromuscular system. The object is attained by the stimulation of osteoclastic activity in bone so that the balance normally maintained between deposition and absorption of calcium is upset and calcium salts are released to the blood in increased quantities.

It is not necessary to ascribe any further direct action to the parathyroid hormone for the results of interference with the supply of hormone available either in clinical or in experimental conditions will follow from this primary effect. Suppose the supply of hormone is deficient. Osteoclastic activity is retarded and since osteoblastic activity proceeds unchanged there is a lowering of serum calcium resulting in clinical tetany and reduced calcium excretion. It is generally found that the concentration of inorganic phosphorus in plasma varies inversely as that of calcium possibly as an expression of the law of mass action. Hence a further feature will be a high plasma inorganic phosphate content. The only other result which might logically be expected would be an increase in calcium content of bone. Tetany is an acute condition which must be treated at once so that it would be impossible to demonstrate such increase of calcium content. It would be very interesting to know if any patient with chronic parathyroid deficiency who had lived for a considerable time while receiving calcium injections showed any observable increase in density of x-ray shadows.

Events parallel to those in the above sequence follow a prolonged increase in available parathyroid hormone. There is a stimulation of osteoclastic activity so that absorption of calcium from bones outruns deposition resulting in an increase in serum calcium. This in turn causes a reduction in muscle tone and increased calcium excretion and lowered plasma inorganic phosphate. The condition can continue either experimentally or clinically long enough to produce a definite reduction in bone calcium as shown by x-ray shadows by loss of strength and by appearance on direct examination.

### Hypoparathyroidism

In man clinical hypoparathyroidism and hyperparathyroidism present further features which call for special consideration. Hypoparathyroidism may result either from removal of parathyroid tissue during an operation on the thyroid or from a spontaneous loss of function of

and in both cases the primary fall of serum calcium gives rise to those secondary changes referred to above. Outstanding among these is the increased neuro-muscular excitability or tetany. In the post-operative type symptoms begin twenty-four to seventy-two hours after operation, and generally vary in severity with the reduction of serum calcium. The severity seems to be more closely related to the difference between pre-operative and post-operative values of serum calcium and the rate at which serum calcium falls than to the absolute value at the time tetany sets in. Thus in a person whose blood calcium was constantly in the neighbourhood of 14 mg per 100 ccm before operation, removal of a nodule of hypertrophied parathyroid tissue caused an immediate fall of serum calcium to 8.5 mg, which resulted in tetany, although people whose serum calcium had been normal do not develop tetany until a value of about 7 mg per 100 ccm has been reached. The condition may at first be latent—that is, neuro-muscular excitability is demonstrated only by the application of specific stimuli, as in Trousseau's and Chvostek's signs. Later the skeletal muscles develop spasms, apparently spontaneously. The characteristic attitudes produced in the forearms and hands, and often in the legs and feet, have given rise to the term carpo-pedal spasm. Disorders of sensory nerves producing tingling sensations in upper and lower limbs are present early in a number of cases. Patients who have suffered from hypoparathyroidism for some time are said to develop subjective manifestations: they tend to become hysterical and to be unduly depressed even between acute attacks. In rare cases cataracts may appear.

#### POST OPERATIVE TETANY

Post operative tetany is often due to temporary interference with the blood supply of the glands, and will rectify itself when an adequate supply is re-established. Only in those instances where a considerable amount, say 50 per cent, of the total parathyroid tissue is removed will tetany persist. In both cases the logical treatment is injection of parathyroid extract to make good the deficiency in the natural supply and the administration of calcium to correct as quickly as possible the lowering of serum calcium.

The essential factor in the production of tetany is a low serum calcium, and any condition which produces this will lead to increased neuro-muscular excitability like that found in parathyroid deficiency. Thus any interference with calcium absorption, such as is produced by an excess of fatty acid in the intestine or by a deficiency of vitamin D, will operate in this way. An interesting point which has been made in connection with the tetany associated with vitamin D deficiency is the lack of parallelism between the severity of the rickets and that of the tetany. In a series of cases of tetany published by Guild (1933) 58 per cent had very mild rickets, while only 6 per cent showed really severe bony changes radiologically. No attempt was made in the original paper to account for this peculiarity, but in view of what has been said above a rational explanation could be given as follows. In one type of case suffering from lowered calcium absorption the tendency to the lowering of blood calcium stimulates the parathyroids and calcium is mobilized from bones. Tetany is thus prevented but the bones suffer correspondingly. In another type with less active parathyroids calcium is not mobilized from bones, and the blood calcium falls. Tetany develops but the bones will not be so severely damaged. Since the principal function of the parathyroids is probably to maintain the level of blood

calcium, tetany produced by a low calcium absorption is to be regarded as a sign of relative failure of parathyroid activity under strain. Tetany due to lowered calcium absorption should be treated by improving the factors promoting absorption. Injections of calcium salts and parathyroid extract may be employed, but the latter should be regarded as only an emergency measure.

One other condition may be touched upon before leaving the subject of hypoparathyroidism. A number of authors, of whom Mirvish (1930) may be specially mentioned, claim to have shown that the local pathological condition in otosclerosis is a manifestation of parathyroid deficiency and that the disease may be successfully treated by injection of extract. But the figures given for serum calcium by this author are normal, and other workers have failed to produce permanent benefit consistently by this treatment.

#### Hyperparathyroidism

Hyperparathyroidism may be brought about by injection of the extract of the parathyroids or by the local manufacture of an excess of the hormone by parathyroid tissue. In animals the prolonged injection of the extract produces the effects summarized above. In man it is not possible or desirable to continue the experiment long enough to produce obvious bony changes, but a good deal of information has been obtained from cases of lead poisoning treated by parathyroid extract. Here lead is deposited in the skeleton, and this acts as a reservoir long after the supply from outside has been cut off. Injection of parathyroid extract causes a rise in serum calcium, with increased calcium excretion. At the same time evidence of its action on the bones is produced by the increase in excretion of lead and its disappearance from these reservoirs.

Clinical hyperparathyroidism due to an increased local production of the hormone by a tumour has recently assumed special interest in view of the discovery that it is responsible for generalized osteitis fibrosa cystica. Although this was described in 1891 by von Recklinghausen, and post-mortem examination during the early part of this century had repeatedly shown cases to be associated with a parathyroid tumour, it was not until 1926 that Mandl attempted to cure the disease by removal of such a tumour. The case showed the typical features to be described presently, and the operation effected a complete cure. This discovery, taken in conjunction with the observed effects of the injection of Collip's extract, finally established the role of the parathyroids in calcium metabolism, which, in spite of significant observations by MacCallum and others, had not previously been definitely recognized.

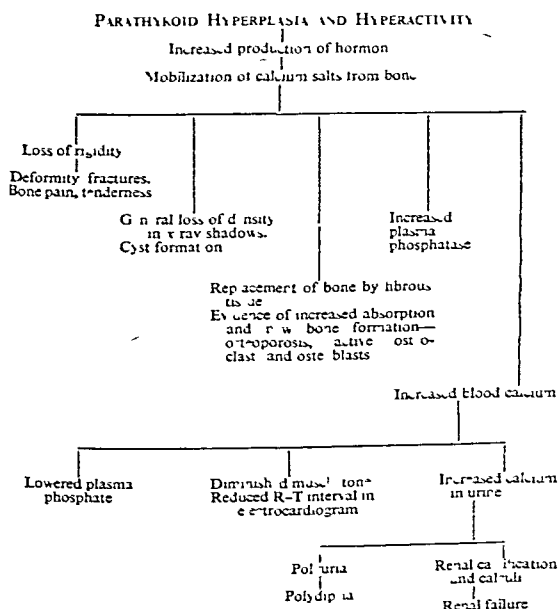

#### The Development of Clinical Hyperparathyroidism

We may trace the development of the clinical condition as follows. The primary effect is stimulation of osteoclastic activity with removal of calcium salts from bones. Secondary effects are produced in the bones and elsewhere. In the bones we find loss of rigidity, leading to deformity, spontaneous fractures, pain, and tenderness. Radiologically and histologically there are lack of density of x-ray shadows, cyst formation, giant cell tumours, replacement of bone by fibrous tissue, and increased osteoblastic and osteoclastic activity with osteoporosis. The general alteration may be quite easily seen with the naked eye, and the bone may be so soft as to be easily cut with a knife.

The more general effects may be largely attributed to the increase in blood calcium which automatically follows removal of this element from the skeleton. Thus plasma inorganic phosphate is lowered, muscle tone is diminished and calcium excretion is increased. The last leads to polyuria which in turn produces polydipsia. The continual passage of urine rich in calcium salts often together with the bedridden condition of the patient leads to deposition of calcium salts in the kidney either diffusely in the cortex or as one or more renal calculi. Deposits of calcium phosphate may also be found in the lungs.

A further interesting feature of this condition is the great increase of plasma phosphatase. This enzyme is concerned in the hydrolysis of esters of phosphoric acid with the liberation of inorganic phosphate. It normally occurs in greatest quantity in osteogenic tissues and is found in blood only in very small concentrations. In hyperparathyroidism it is present in plasma in five to ten times the normal values and we assume that this is due to a marked compensatory activity of osteoblastic tissue. Certain American workers—for example Ballin (1932)—have described a reduction of the R-T interval in the electrocardiogram. This they suppose to be a direct effect of the raised blood calcium on the relaxation of the heart.

The sequence of events may be represented diagrammatically as follows:

The victim of the fully developed condition is thus not infrequently a confirmed invalid who has been much restricted in activity or completely bedridden perhaps for years. In the absence of treatment death often from renal complications was the rule. The dramatic improvement after removal of the tumour is therefore all the more striking. The blood calcium falls often so rapidly that symptoms of tetany supervene and require treatment by injections of calcium salts or parathyroid extract. Blood phosphate and calcium excretion return to normal while bone pain and tenderness and muscular atony disappear and the patient regains strength and weight rapidly. The bones return to normal more slowly but

definite increase in density is generally apparent in six to twelve months. The cysts may decrease in size and there are no more spontaneous fractures. In short the patient has always been improved and has in many cases been enabled to lead an active useful life.

When the condition was first recognized it was thought that hyperparathyroidism might prove to be a no longer common complaint as many clinicians realized almost immediately that they had cases already under their care but general experience indicates that it is quite rare. In Dublin only six cases proved by operation or necropsy and full investigation have been seen during the last 25 years. Three of these have already been described in detail by me (1936).

It has also been stated that a parathyroid tumour is a frequent cause of renal calculi. Colby (1934) has recorded three cases in two of which no bone change was detected radiologically but which showed a raised serum calcium. A parathyroid tumour was found in each case and was removed and in one the calculus disappeared after operation. But in the urological department of the Meath Hospital Dublin during the last five years every patient with urinary calculi has been investigated from this point of view and not one case has been found.

Several attempts have been made to include other bone diseases such as osteitis deformans, osteogenesis imperfecta and polyarthritides as manifestations of hyperparathyroidism but the evidence adduced is in no case conclusive. Certainly in several cases of osteitis deformans and in one case of osteogenesis imperfecta we found no biochemical evidence of increased parathyroid activity and in the last mentioned a post mortem examination failed to reveal a parathyroid tumour.

The Proceedings of the Second International Scientific Congress on Nutrition have been published under the title *La Science de l'Alimentation en 1937* (Alimentation Imprimerie Alenconnaise). Among the numerous resolutions adopted by the congress were the following: (a) tables of analysis of foods in terms of minerals, vitamins and indispensable organic compounds should be drawn up and periodically reviewed in every country; that it was desirable to popularize the rules of a rational diet based on modern scientific knowledge and to establish closer relations between (a) physiologists and doctors, (b) public authorities and (c) families and educational establishments; that children should not have more than 1 litre of milk a day; that in homes for infants in schools etc bread pastries dried vegetables pork and recocked meats should to a large extent be replaced by fresh vegetables and fruits; that from the age of 5 years it was necessary to give an abundant ration of animal protein; that a child of 12 needed a diet as nutritive and as varied as that of an adult; and that a boy or girl of 16 required a greater amount of food than the average adult of either sex. Various resolutions were also passed which emphasized the importance of continuing investigations in different countries into the diet of people of different professions and occupations, the importance of education in dietetics, the need for legislation for preventing the misuse of food, the importance of refrigeration and the control of adulterants which exaggerated the good effects of vitamins.

# LABORATORY AND CLINICAL INVESTIGATIONS ON TUBERCULIN PURIFIED PROTEIN DERIVATIVE (P.P.D.) AND OLD TUBERCULIN (O.T.)

The value of the Mantoux test as a clinical aid seems to be doubted in some quarters, apparently on the assumption that there is almost complete tuberculinization of the population. This may still be true of crowded urban districts but recent epidemiological surveys have shown that in many communities a large percentage of people reach adolescence without having been infected, and, moreover that this percentage is becoming greater as the incidence of tuberculous disease is decreasing. There can be little doubt therefore that with time the Mantoux test will be found more and more useful in clinical work.

Since the Mantoux test is a quantitative one, the material used in its performance should be stable, and constant in composition and potency, further the exact amount of the active principle injected should be known. Only if these conditions are fulfilled will it be possible to compare repeated tests at intervals on the same patient, and to correlate or pool the observations of different workers investigating large groups. Until a few years ago Koch's old tuberculin was always used, but it was increasingly realized that this crude material did not fulfil the conditions laid down above.

Old tuberculin is usually prepared by the growth of the tubercle bacillus on a veal-infusion-peptone medium containing a comparatively large amount of glycerol. The mature culture is steamed and the filtrate evaporated to one-tenth of its original volume. Thus it is a complex mixture, containing besides the active principle, much non-specific material such as peptones salts glycerol, and bacillary metabolic products. Long (1934) has stated that its potency is due to about 1 per cent of its total substance. It has been found that batches of old tuberculin prepared not only from different strains, but even from the same strain and in the same type of culture medium may vary in potency. Moreover no accurate method of standardization has been developed. The shock method, which was found to carry a large error was replaced by intracutaneous testing in guinea pigs but even this may allow a 40 per cent error unless a large number of comparisons are made (Oxell and Parish 1927). Finally, the use of old tuber-

culin has the disadvantage that dilutions deteriorate comparatively rapidly.

These considerations have stimulated much research work, particularly in America, to eliminate non specific factors and thus prepare a purer product. The first important step was made when Long and Seibert (1926) showed that the tubercle bacillus would grow and produce a potent tuberculin on a synthetic medium with asparagine and ammonium salts as the sole sources of nitrogen. It was found that protein-like substances were formed during growth on this medium and this led to the view that the active principle was of a protein nature, as suggested much earlier by Koch. Definite confirmation was obtained by Seibert (1928), who prepared unheated culture filtrates of the organism grown on Long's medium, and was able to isolate a crystalline protein which is water-soluble and a very active tuberculin. Repeated recrystallization of this product increased rather than decreased its potency, demonstrating conclusively the protein nature of the active principle. This method is impracticable for the routine production of a pure tuberculin for the following reasons: (1) the amount of tuberculo-protein which will crystallize is very small, (2) the protein which will not crystallize is also physiologically active, (3) when the product is injected there is some risk of producing sensitization which might lead to errors in reading. In this connexion Seibert (1933) has shown that it is possible to isolate the active principle in different states of molecular aggregation according to the method of preparation. Potent tuberculin preparations, all of a protein nature, have been made with different molecular weights—namely (a) ammonium sulphate fraction from unheated culture filtrates (Seibert's TPA)—molecular weight = 25,000, (b) trichloroacetic acid precipitate from unheated culture filtrates (Seibert's TPT)—molecular weight = 3,000 to 8,000, and (c) trichloroacetic acid precipitate from steamed and evaporated culture filtrates (Seibert's SOTT—"synthetic medium old tuberculin trichloroacetic-acid-precipitated")—molecular weight = 2,000. The sensitizing power of these preparations has been investigated, with the exception of SOTT which possesses the lowest molecular weight, they are capable of eliciting reactions of the Arthus type when injected repeatedly into the skin of guinea-pigs and of producing precipitins in rabbits. Obviously it is undesirable to use preparations with which there is the slightest risk of sensitization, for they may lead to erroneous results (Aronson and Nicholas, 1933), the best diagnostic agent so far produced is therefore the non sensitizing SOTT, which Seibert (1934) has more recently named "purified protein derivative". This is simply the substance of the lowest molecular weight which will cause the tuberculin reaction in sensitive subjects. It is isolated as a dry powder, any desired doses of which can be issued to doctors in sterile form in bottles or in the shape of tablets. Solutions are made up very conveniently as required. It is claimed that PPD is always of the same composition and potency. Variation in strain of bacillus or luxuriance of growth merely causes variation in yield of PPD. Thus an exact known quantity by weight of the effective substance is always injected. The other advantages claimed are absence of non-specific substances, increased stability, and the convenient preparation of dilutions.

## I LABORATORY INVESTIGATIONS

By F. V. LINGGOOD and H. J. PARISH

In this section we propose to deal with the preparation, potency, and stability of purified protein derivative (P.P.D.) and of "dried dilutions" of P.P.D.

### Preparation of Purified Protein Derivative

We have adhered closely to Seibert's method (1934). The bacillus is grown on a synthetic protein free medium from which an old tuberculin is prepared by steaming and evaporation. The bulk of the impurities is removed by ultrafiltration and the active principle precipitated with trichloroacetic acid. The precipitate is thoroughly washed with this reagent and the acid is then removed with ether which at the same time dehydrates the protein derivative.

For those who are specially interested in the method of preparation technical details are as follows:

A suitable strain of tubercle bacillus is grown as a film in large 20 litre (rose water) bottles on the synthetic medium of Long and Seibert (1926) which in our hands has given a better product than certain other synthetic media. After two to three months the mature cultures are killed by steaming for two hours and the organisms are then removed by filtration through paper pulp. Glycerol is added in the proportion of 122 ccm to each litre of original culture fluid and the mixture is evaporated on a steam bath to one fifth to one tenth of its original volume. This concentrate is diluted with an equal volume of 1 per cent phenol in distilled water left in the cold room for some days for any precipitate to collect and then filtered warm through a Berketeld candle. By this means a synthetic medium old tuberculin is produced which has now to be freed from all extraneous matter.

A preliminary purification is made by ultrafiltration using the technique described by Quigley (1934) except that a special collodion is used (ICI H445 as a 13 per cent solution in glacial acetic acid).

The synthetic medium old tuberculin prepared as above is diluted with an equal volume of 0.5 per cent phenol water and drawn through the ultrafilters. The active principle remains outside the filters while salts, glycerol, amino acids and other non colloidal constituents of the crude tuberculin pass through the membranes. Washing with 0.5 per cent phenol water is continued until the ultrafiltrate is practically chloride free.

The solution outside the membrane concentrated to a small volume consists mainly of the active principle bound to polysaccharide. The latter is removed by the addition of one quarter volume of freshly prepared 50 per cent trichloroacetic acid. The resulting precipitate which consists almost entirely of the pure protein derivative (Seibert 1932) is collected by centrifugalization and washed six to eight times with fresh 10 per cent trichloroacetic acid to remove the contaminating polysaccharide.

After the final washing the precipitate is smeared rather thickly inside the centrifuge tube and the excess of water is removed by drying *in vacuo* for half an hour but complete drying must be avoided. (From this stage onwards great care must be taken to prevent any of the powder being inhaled by the manipulator. All operations are conducted inside a box with a closely fitting glass lid and sleeves to protect the arms of the manipulator. Suction from a water pump is gently applied to one side of the box to prevent any of the powder diffusing around the lid into the air of the room. As a further precaution rubber gloves and a respirator should be worn.) Large volumes of dry ether are used to extract the water and trichloroacetic acid from the precipitate by alternate trituration and decantation through a Soxhlet thimble. The process is repeated until the precipitate is in the form of a very fine powder. By this time it will be found that the ether coming through the Soxhlet thimble gives no acid reaction. The fine powder is transferred to the thimble and is thoroughly washed again with dry ether. The thimble is then placed over paraffin wax in a desiccator and the last traces of ether removed *in vacuo*. As tuberculin adheres tenaciously to filter-candles and glassware (Parish and O'Brien 1935) the apparatus in the tuberculin laboratory must on no account be employed for other biological work.

### Potency and Stability of Purified Protein Derivative

The dry purified protein derivative is a tan-coloured powder. Although minor variations have been noticed occasionally the potency of different preparations has been remarkably constant. When redissolved at a concentration of 5 mg per ccm successive batches almost invariably have been equal in potency to the international standard old tuberculin on guinea pig intracutaneous test. The solutions for these tests are prepared by the addition of a small amount of N/10 alkali to the powder in order to dissolve it. Borate buffer solution is added subsequently and the pH adjusted to 7.4; the final concentration being 5 mg per ccm. The dry purified protein derivative is a very stable preparation.

### 'Dried Dilutions' of Purified Protein Derivative: Preparation, Potency, and Stability

In America the active principle is incorporated in tablets with a dry diluent, beta lactose (Reichel and Clark 1934) and issued in two strengths. We have adopted a somewhat different procedure. The dry powder is weighed and dissolved as described above to give a final strength of 5 mg per ccm. The potency of the material after filtration through a Berketeld candle is checked on tuberculous guinea pigs on a number of occasions to ensure that it is equivalent to international standard old tuberculin. The standardized solution of P.P.D. is then diluted under sterile conditions in a special boric acid buffer solution of pH 7 the final dilutions being distributed in bottles which contain 1 ccm (ten doses of 0.1 ccm) of strengths equivalent to 1 in 10,000, 1 in 1,000 and 1 in 100 of international standard old tuberculin. These dilutions are evaporated to dryness *in vacuo* under sterile conditions. Immediately before use 1 ccm of a special borate diluent is added to the required bottle which is left stoppered for two minutes for the dried dilution to dissolve and is then well shaken. The strength of the boric acid borate and salt in the final diluent is adjusted so that the final mixture is isotonic and of pH 7.4. The dose of the reconstructed dried dilution is 0.1 ccm. The actual weights of P.P.D. prepared for injection are 0.00005 mg (that is 0.1 ccm of dilution 1 in 10,000), 0.0005 mg and 0.005 mg.

Before issue from the laboratories the potency of each batch of dried dilutions is tested on tuberculous guinea pigs against freshly prepared dilutions of international standard old tuberculin. For these tests the dried dilutions are redissolved in the special diluent and may then be diluted further in physiological saline to provide a suitable range of dilutions for the injections. Thus a dilution of 1 in 500 is generally prepared from the 1 in 100 dried dilution and dilutions of 1 in 2,000 and 1 in 4,000 from the 1 in 1,000 dried dilution. Checking the potency of the 1 in 10,000 dried dilution is only practicable on very sensitive guinea pigs. So far we have been unable to detect any loss in potency during preparation or after storage for three years at room temperature. A more serious solution however of error is more rapid than that of corresponding dilutions of old tuberculin.

With reference to the particular dried dilutions of P.P.D. which were used in the following clinical study our aim was to make them as nearly equal to the corresponding dilutions of old tuberculin as possible. Actually they proved to be very slightly stronger although this difference was apparent only after repeated tests on the

skin of very sensitive guinea-pigs. Altogether forty-six guinea-pigs have now been used, with the following results

PPD = O.T. on 12 guinea pigs  
 " > " ; 22 "  
 " < " ; 12 "

We would emphasize that the difference between the dilutions of the two preparations was not detectable on all the guinea pigs and that only our most sensitive animals indicated that the dilutions of PPD were a trifle stronger. Twofold differences were clearly distinguishable on the whole of the guinea-pigs, and it was agreed by all who observed the reactions that the difference in potency indicated in the above table was very much less than twofold.

## II CLINICAL INVESTIGATIONS

### (a) Mantoux Tests. A Comparison of Purified Protein Derivative with Old Tuberculin

The present investigations were undertaken to compare PPD with old tuberculin in clinical work. At first sight this is absurd since we are apparently comparing two substances made comparable by standardization. But since the standardization is carried out in guinea-pigs, such an investigation is still indicated in man, and might serve to emphasize any deficiencies of the guinea-pig standardization. Preliminary tests on human subjects made previously by Davis and Guzzard (1935) and Westwater (unpublished) have shown that 'wet' dilutions of PPD deteriorated more rapidly than corresponding dilutions of old tuberculin and were thus unsuitable for use. Therefore, as mentioned earlier in this paper, 'dried dilutions' of PPD and also a suitable borate buffer diluent were supplied to us from the Wellcome Laboratories. Corresponding dilutions of old tuberculin in 0.5 per cent phenol saline were also provided, and, on account of the possibility of deterioration, were used within a fortnight (very occasionally three weeks) of receipt.

Particular care was taken in performing the tests and in recording the results. The usual technique was followed—that of injecting 0.1 c.c.m. intradermally, choosing comparable sites on each forearm, and, in view of the extreme 'tenacity' of tuberculin to glass (Parish and O'Brien, 1935) separate syringes were reserved, and employed for each type of tuberculin and for each individual dilution. Some of us found that for accurate work it was helpful to have only one dose in the syringe at a time—that is the tuberculin drawn up to the 0.1 c.c.m. mark—so that attention could be concentrated on raising a proper intradermal wheal.

The reaction to the intradermal injection of 0.1 c.c.m. of tuberculin in a sensitized person is an erythema, an erythematous infiltration or an actual oedema of the skin, usually at a maximum after forty-eight hours and varying in size. Mild reactions may present difficulty in interpretation and there is no universal agreement on what constitutes the minimum reaction to be accepted as positive. Different authorities have taken as suitable criteria areas of erythema varying in diameter from 2 mm to 10 mm, with or without associated infiltration. In addition there is considerable difference of opinion concerning the best time to read results, but most workers agree that a twenty-four hour reading is not reliable. Hart (1932) accepts as a positive reaction an erythema or erythematous infiltration whose greatest diameter is 5 mm or more taking the forty-eight hour reading, and Aronson (1934) has a similar standard. Holm (quoted by Kayne, 1936) requires

at least an infiltration of 7 mm diameter at forty-eight hours, or 5 mm at seventy-two hours, for a positive reaction. Kayne (1936) adopts the following criteria in considering a reaction positive:

At 48 hours area of erythema, with or without swelling, 10 mm in diameter (mean)  
 At 72 hours area of erythema and swelling, 7 mm in diameter (mean)

#### TESTS BY G. GREGORY KAYNE

The erythema and swelling cannot always be measured with accuracy, and the "experimental error" of the size of the reaction has not been determined. It appeared, therefore, that as the object of the present investigation was to assist in clinical work, the comparisons should be based on the relative number of positive and negative reactions. The criteria adopted in considering a reaction positive with either substance are given above.

A total number of 119 persons were tested with old tuberculin and PPD at comparable sites on each forearm. 114 were adult patients at the Clare Hall Sanatorium, Middlesex, all of whom except three suffered, or had recently suffered, from active pulmonary tuberculosis, the remaining five belonged to the domestic staff, and were healthy (three of them proved negative to all dilutions of both substances). All the results were read after twenty-four, forty-eight, and seventy-two hours, and the reactions were carefully measured. The subjects were injected first with the highest dilutions—namely, 1 in 10,000 of each preparation. If the tests were negative or doubtful they were repeated with the next stronger dilution. The results are as follows:

TABLE I—Summary of Tests with Purified Protein Derivative and Old Tuberculin

	Dilutions		
	1 in 10 000	1 in 1 000	1 in 100
PPD - O.T. -	26 patients	7 patients	4 patients†
PPD - O.T. -	63	24	2
PPD - O.T. -	29	1	0
PPD - O.T. +	1	0	0

\* Some of the tests with 1 in 10 000 that were only just positive were repeated with 1 in 1 000.

† Three of these persons belonged to the domestic staff, the fourth was a tuberculous patient who died two days later.

TABLE II—Variation of Readings (48 and 72 Hours)

Negative at 48 hours positive at 72 hours	{ PPD 3 patients O.T. 7
Positive at 48 hours negative at 72 hours	{ PPD 3 O.T. 4

Note.—In each of these four groups were tests with both the 1 in 10 000 and the 1 in 1 000 dilutions.

An appreciably greater percentage of positive reactions is obtained with PPD than with old tuberculin (Table I). A few reactions did not appear till seventy-two hours after the injections (Table II), and, with both old tuberculin and PPD, reactions occasionally occurred at twenty-four and forty-eight hours, which disappeared twenty-four hours later.

#### TESTS BY A. T. DOIG, G. GEMMILL AND J. S. WESTWATER

In the present investigation we adopted the following minimum standard to be accepted as a positive reaction: an erythema of at least 10 mm or an infiltration of at least 5 mm, in either case persisting for forty-eight hours. Reactions less than that were considered negative. We consider it would not be safe to accept a simple erythema under 10 mm as a positive reaction without confirming the result by using a stronger dilution. It

should be noted that it is rare to have a 5 mm infiltration without some surrounding erythema

By taking the forty eight hour reading any transient erythema arising from needle trauma is excluded as this does not last longer than twenty four hours. In this section of the work the forty eight-hour reading being usually the maximum was taken as the standard for comparison of the two tuberculins and the mean diameter was recorded in millimetres. In order to allow for errors of technique it was decided to regard as equal those reactions in which the mean diameter of the larger did not exceed that of the smaller by more than 25 per cent.\*

A total of 302 subjects have been tested the majority in the course of routine diagnostic work on children and adults. Of these 241 can be considered adequately tested—that is negative reactions were checked up to the 1 in 100 dilution—and 228 reacted to either or both forms of tuberculin.

In Table III the results are compared by measurement of the mean diameter. In 60.1 per cent the reactions were equal in 27.2 per cent the reaction with PPD was the

greater, the indication of greater potency of the dilution of PPD is repeated.

It is important to note that despite the allowance of 25 per cent in measuring the reactions to cover experimental error there is considerable divergence in the results showing that if the Mantoux technique is to be used as a means of standardization it is necessary that tests be made on considerable numbers of patients before any reasonable assessment of potency can be made. Maden and Holm (1935) consider the intracutaneous test in humans a method of standardization preferable to test in the sensitized guinea pig. The necessity for a large series however has to be met. Multiple tests on the one subject have obvious objections although Philip (1930) considered it a practical method using serial dilutions with the cutaneous (Pirquet) technique.

The reactions obtained from PPD are similar in character to the response to old tuberculin. They could not be said to be more clear cut and easier to interpret.

#### (b) Mantoux Tests. Additional Investigations The Stability of Old Tuberculin

1 TESTS BY G. GREGORY KAYNE

On the basis of tests on guinea pigs Parish and Okell (1929) and Okell (1930) found that dilutions (1 in 100 to 1 in 4000) of old tuberculin in saline had lost about 40 per cent of their potency after three months' storage at 4°C at room temperature or at 37°C. As a working rule they consider that sterile dilutions of old tuberculin in saline may safely be used even after being kept for one month at room temperature. Douglas and Hurtle (1934) detected no loss of activity when dilutions of international standard old tuberculin in 0.5 per cent phenol saline were stored at 2°C and at room temperature for fifty-three days. Deterioration was observed however when they were stored at 37°C for fifty-three days.

The opinion is commonly expressed nevertheless that dilutions of old tuberculin should not be used when more than two weeks old. Mantoux tests in human subjects were therefore carried out to investigate this statement and a test made of the stability of dilutions of international standard old tuberculin in 0.5 per cent phenol saline kept at various temperatures.

The different dilutions were used orally—that is they were labelled with symbols at the Wellcome Laboratories and the key was supplied to me later. This procedure is necessary so as to avoid the influence of preconceived ideas in reading reactions that are not sharply outlined. Since as many as four injections were made on one arm the order in which dilutions were injected in each patient was varied to obviate the possible influence of the texture of the skin. Readings were taken at forty-eight and seventy-two hours and for these investigations a dilution of 1 in 10,000 was used.

The results are shown in Tables V and VI.

TABLE V—Three Dilutions of Old Tuberculin kept in the Ice-chest 9 Weeks, 7 Weeks and 5 Weeks respectively and a Dilution Prepared the Day it is Used

Readings	Results (Number of Positive Reactions)			
	Fresh	5 weeks old	7 weeks old	9 weeks old
At 48 hours	15	15	17	17
At 72 hours (19 patients only read)	15	17	15	17

Allowing for some experimental error in reading, there appears to be no deterioration of the tuberculin even after nine weeks at 4°C.

TABLE III—Comparison of Purified Protein Derivative and Old Tuberculin by Measurement of the Mean Diameter of Reactions

Comparison of Mean Diameter	Dilution						Total	Per Cent	
	1 10 000			1 1 000					1 100
	A 1 D	G G	J S W	A 1 D	G G	J S W	A 1 D	G G	J S W
PPD = OT	44	23	19	14	20	3	7	2	-
P.P.D > OT	25	15	3	10	6	-	2	1	-
† PPD < OT	11	4	4	5	2	2	1	-	-
	Total						228	100	

\* Includes 24 cases in which reaction to PPD was positive and to OT negative.

† Includes 5 cases in which reaction to PPD was negative and to OT positive.

greater while in 12.7 per cent it was smaller than the response to old tuberculin. This would suggest that the dilutions of PPD were slightly more potent as they appeared to be in tests on guinea pigs. The possibility of the greater stability of PPD being a factor in eliciting a stronger reaction must be borne in mind although the care taken to use the dilution of the old tuberculin within three weeks of preparation was considered to eliminate this

TABLE IV—Comparison of Purified Protein Derivative and Old Tuberculin by Incidence of Positive and Negative Reactions

Reactions	ATD	GG	J.S.W.	Total	Per Cent
PPD + OT +	97	64	35	196	86.0
PPD - OT -	19	7	—	26	11.4
PPD - OT +	3	2	1	6	2.6
	Total			228	100

factor and Kayne's and Doig's observations (given below) confirm this view. In Table IV comparing the tuberculins simply by the incidence of negative and positive

\* Twenty-three subjects were injected by one of us (G.G.) in both arms at comparable sites with the same material taken from the same batch—namely 0.1 ccm of PPD diluted 1 in 1000 or for some tests 1 in 10,000. The difference in the mean diameter of the individual reactions on both arms was usually 2 mm or less the extreme difference being 6 mm in one comparison. The mean of the mean diameters of all the reactions on right and left arms respectively were almost identical—namely 22.4 and 22.6 mm. These results suggest that the margin of error—namely 25 per cent difference—was adequate which was taken into consideration for the comparison of PPD and old tuberculin.

TABLE VI—Four Dilutions of Old Tuberculin kept at Room Temperature (22° C) for 11 Weeks at 37° C for 11 Weeks at Room Temperature for 7 Weeks and at 37° C for 7 Weeks Respectively

Results (Number of Positives)					
Patients Read	At 48 Hours		Patients Read	At 72 Hours	
	Fresh	11 weeks 22° C		Fresh	11 weeks 22° C
20	14 (70%)	10 (50%)	20	16 (80%)	9 (45%)
26	Fresh 18 (70%)	11 weeks 37° C 9 (35%)	26	Fresh 17 (65%)	11 weeks 37° C 11 (42%)
23	Fresh 17 (74%)	7 weeks 22° C 14 (61%)	22	Fresh 12 (54%)	7 weeks 22° C 12 (54%)
22	Fresh 16 (73%)	7 weeks 37° C 12 (54%)	21	Fresh 15 (71%)	7 weeks 37° C 12 (57%)

Since I consider the reading at seventy-two hours should be the one adopted for the Mantoux test, it appears that there is no deterioration of the tuberculin kept for seven weeks at room temperature, but definite deterioration occurs if kept for this period at 37° C. After eleven weeks there is definite deterioration if the tuberculin is kept at either of these temperatures.

In conclusion, the common opinion that dilutions kept for two weeks should not be used errs very much on the side of caution. Dilutions may be employed with safety up to six weeks, at all events if kept at room temperature, and for nine weeks if kept in an ice chest.

## 2 TESTS BY A. T. DOIG

On the lines described above a test was made of the stability of 1 in 10,000 dilutions of old tuberculin kept at 4° C for four weeks and for eleven weeks. The injections were made about the middle of the forearm (one on the right arm and two on the left), and in the same order on each patient. The skin in the elbow and wrist regions was avoided, but otherwise possible differences in the texture of the skin were disregarded.

Twenty-six patients were tested, of whom four did not react to any of the dilutions. The readings, taken at forty-eight hours, were

1 in 10,000 dilution OT	3 days old	21 positive (1 doubtful)
	4 weeks old	22
	11 weeks	21

It is therefore concluded that old tuberculin, even in dilutions of 1 in 10,000 is a considerably more stable substance than is commonly believed, and storage for as long as eleven weeks at 4° C causes little appreciable loss of potency.

## Experiment to Test the Accuracy of the Mantoux Test with Old Tuberculin

BY G. GREGORY KAYNE

When one of the dilutions investigated was 1 in 10,000 of international standard old tuberculin a 40 per cent difference in potency between two dilutions was barely detectable, although a 60 per cent difference had an appreciable influence on the number of positive reactions obtained (Table VII).

The differences in potency shown in the table suggest that we should examine once again the results of the Mantoux tests with PPD and old tuberculin presented earlier in this paper. It will be remembered that the dilutions of the two preparations supplied from the Wellcome Laboratories were about equal in potency on intracutaneous tests in guinea pigs; differences in the size of

the reactions were trifling, PPD appearing to be the stronger only on the most sensitive animals.

TABLE VII—Four Dilutions of Old Tuberculin 1/10,000 1/12,500 1/16,600 and 1/25,000 Corresponding to 100 per cent 80 per cent 60 per cent and 40 per cent of a Dilution of 1 in 10,000

	Results (Number of Positives) in 24 patients			
	100%	80%	60%	40%
At 48 hours	16	18	17	13
At 72 hours	19	19	17	12

It is perhaps worthy of comment that few tuberculous guinea-pigs are sensitive to 1 in 10,000 dilutions of tuberculin, whereas many patients in sanatoria give large positive reactions to this dilution.

We are indebted to Dr. J. W. Trevan for the following statistical note.

The experiments on guinea-pigs recorded earlier in this paper show a distribution which would, I calculate, occur by accident about eight times in a hundred trials on groups of forty-six guinea-pigs. Any difference between PPD and OT for the guinea pig is therefore not large enough to be established by the use of forty-six guinea-pigs with the degree of probability that is usually taken as significant, but the results are suggestive.

The experiments recorded in Table III (228 patients), whether the total or only the 1 in 10,000 dilution figures are used, give a highly significant excess of PPD > OT over PPD < OT. It can be taken as established that PPD in the doses used is more potent than OT. This is borne out by Table I (119 patients) and Table IV.

But it cannot be established that PPD is more potent than OT for man when given in doses which are identical on guinea-pigs, for there are more observations on man. It must not be assumed that since the differences in man are highly significant whereas those on the guinea pig are not significant by the ordinary criterion, there is a real difference between the relative potencies on man and on the guinea pig. Further multiplication of tests on the guinea pig might quite well result in the establishment of a significant difference between the dilution doses of PPD and OT used for that animal.

## Summary and Conclusions

1 Attention is directed to purified protein derivative (PPD) as the most suitable reagent for the Mantoux test. It is the active principle isolated in a pure state as a dry powder from a synthetic medium old tuberculin. It corresponds to Seibert's SOTT (synthetic medium old tuberculin trichloroacetic-acid-precipitated). It is almost invariably of constant potency on a weight basis, is very stable in the dry state, and is of a non-sensitizing nature. It is therefore particularly suitable for use in large scale surveys where uniformity in the amount of the active principle injected is essential.

2 'Dried dilutions' which are likewise of uniform potency and quite stable can also be prepared from PPD. As a precautionary measure the potency of these dried dilutions is checked from time to time against the international standard old tuberculin, the intracutaneous test in the tuberculous guinea pig being used for the comparisons. On no occasion has any variation been observed from the calculated potency. The dried dilutions may be redissolved easily and quickly in a suitable borate buffer solution immediately before use.

3 A series of dried dilutions of PPD have been compared with corresponding dilutions of international

standard old tuberculin by means of the Mantoux test the two tuberculins having been titrated previously on sensitive guinea pigs. On intracutaneous test in a large number of guinea pigs the preparations were almost equal in potency, only the most sensitive animals indicating that the dried dilutions were a trifle stronger.

4 The reactions obtained with PPD were very similar in character to the response with old tuberculin both in guinea-pigs and in human subjects.

5 Clinical comparison both by measurement and by the relative number of positive and negative reactions obtained indicated that the PPD was slightly more potent than the old tuberculin a fact that was only evident on the most sensitive guinea pigs.

6 The results of the four clinical workers suggest that if the Mantoux test were to be used as a method of comparing the potency of two tuberculins it would be necessary to have observations on a large number of patients before any conclusion could be drawn. There would appear to be no advantage in using human subjects instead of guinea pigs for the titration of old tuberculin.

7 In practice the deterioration of dilutions of old tuberculin in phenol saline is not sufficient to prevent their use for Mantoux tests if they have been kept up to six weeks at room temperature or nine weeks in the ice chest. Dried dilutions of PPD are much more stable and have shown no detectable loss in potency after three years at room temperature.

W. Knoll (*Med. Klinik*, April 8 1938, p. 464) has followed up the life history of 880 Oxford and Cambridge Blues and refutes the theory that as a rule they die before the age of 50 as a result of the severe strain on the heart during the training period. Of the 880 investigated 27.5 per cent took part in one inter-university boat race 29.7 per cent in two 24.5 per cent in three 14.5 per cent in four and 4 per cent in more than four races. A statistical survey shows that by 1929 five-eighths of all the living participants in the races were above the age of 50 the average age being 61 years and many having reached the age of 70 and over. Of 155 deaths eight were due to infective diseases, seventeen to tropical diseases, twelve to accidents and forty-five died in the war, thus the mortality from natural causes was 81 per cent which figure is relatively low.

## THE CAUSES OF HAEMORRHAGE FROM THE RECTUM\*

BY

J. P. LOCKHART MUMFERY, F.R.C.S.

Emeritus Surgeon to St. Mark's Hospital for Diseases of the Bowel

Visible blood may be passed per anum under a variety of circumstances and from many different causes. Such an occurrence is always alarming to the person concerned and the medical attendant will at once be called upon to give a reason for it and reassure the patient as to its meaning. It will be necessary to account for the bleeding at once or at least to arrange for some examination to be made which will reveal the cause. While it is advisable to reassure the patient, it is never safe to tell him or her that a little bleeding is of no serious consequence and to treat it by ordering a few supportive remedies. Such guesswork methods are dangerous to the patient's well being and to the doctor's reputation. It is therefore of some importance to consider the various causes of the haemorrhage and how the source and reason for the bleeding may best be ascertained.

Naturally a large haemorrhage will give rise to much more alarm than a small one, but it does not follow that the former condition is the more serious or has the gravest significance. Any bleeding, whether small in quantity or not, calls for immediate attention and should never be neglected as not infrequently very slight intermittent bleeding is the first sign of a malignant growth somewhere in the intestinal tract, nor is it safe to assume that because the patient is quite a young person malignant disease can be ruled out. I have seen a child of 8 years with carcinoma of the rectum and although the condition is rare under the age of 40 there are quite enough cases to make us very cautious.

It is a curious and not unimportant fact that patients who have suffered for some months from what they describe as slight bleeding at stool often exhibit a much more serious degree of anaemia than those who have had one large haemorrhage. The probable reason for this is that patients are prone to attach much more importance to small, often repeated bleedings than to a single severe one.

### Internal Piles

The commonest cause of haemorrhage from the rectum is unquestionably internal piles and this probably accounts for quite two-thirds of all the cases of bleeding from the rectum. I have seen patients who as the result of frequent haemorrhages due to piles have been blood white and whose blood count had been reduced to under 3,000,000 red cells per cmm. Not long ago I had in this hospital a patient with internal piles who was a professional pugilist. He had been bleeding at stool for over a year and he was so reduced by it that he could hardly walk across a room without feeling faint. His hair was a greenish white and his red cell count was under 3,000,000 per cmm. Before operating for the piles it was necessary to transfuse him with human blood. But such severe anaemia is unusual as the result of piles.

Bleeding due to piles can generally be recognized because a simple examination of the rectum with a speculum will reveal the presence of small prolapsing internal piles and also because the characteristic form of bleeding is for the blood to drip or squirt after the bowel

\* A Postgraduate Lecture given at St. Mark's Hospital on March 10 1938.

has been relieved. It is well to remember that the presence of internal piles does not exclude the possibility of a carcinoma higher up the bowel.

#### Carcinoma

The next commonest cause of bleeding from the rectum is carcinoma. When the blood is coming from a growth in the rectum or colon it is generally mixed up with the stool instead of being passed after it, as is usual with piles, so that the evacuations are red or brown from the presence of blood. The amount of blood, as a rule, is not considerable and often it is present only intermittently. It occasionally happens that a sudden and very severe rectal haemorrhage is the first symptom of a growth in the rectum or colon. When this occurs it is due to the growth having ulcerated into a small artery. I have known several such cases but they form only a very slight proportion of the total cases of carcinoma of the large bowel.

The diagnosis is as a rule readily established if a finger is passed well up into the rectum. Quite 80 per cent of rectal growths occur within reach of the finger, especially if the patient is examined bimanually. If nothing is felt an early examination with the sigmoidoscope should be made. It is hardly necessary to stress the paramount importance of diagnosing a growth in the bowel at the earliest possible moment, when alone a satisfactory chance of curing the patient by operation exists—a chance which will be seriously jeopardized by a delay of some weeks or months. In diagnosing the cause of the bleeding, therefore, the first requisite is to eliminate the possibility of a growth in the rectum or sigmoid, and the only way to do this is by making a careful digital and sigmoidoscopic examination of the rectum. I often find that patients have been examined by means of a barium enema and radiographs when a simple digital investigation of the rectum would have revealed the lesion. An x-ray examination should only be ordered after a digital and sigmoidoscopic examination has given negative results.

Apart from carcinoma of the rectum, an innocent adenoma will cause haemorrhage. The amount and frequency of the bleeding may be quite considerable if the adenoma is a large one. These adenomata can usually be felt by the examining finger, but as they often are soft and velvety they may be missed by those who are not accustomed to examining the rectum. They can, however, be very easily seen if a speculum is passed. They should always be freely removed, as there is grave risk of their becoming malignant. They should be looked upon as a precancerous condition.

#### Peptic Ulcer

Haemorrhage due to a bleeding duodenal ulcer, as is well known generally results in tarry stools or melaena, owing to partial digestion of the blood on its way down the alimentary tract. When, however, the bleeding is very copious, or occurs rapidly, and the bowel is not loaded, the blood may be seen in the stool as bright fresh blood, similar to that which is present when the source of bleeding is in the rectum or lower colon. This is rather confusing, as in the absence of very definite symptoms of duodenal ulcer the source of the blood may be unsuspected. I have known this happen on several occasions, and in one case it was some time before it was realized that the patient was bleeding from a duodenal ulcer and not from his large bowel.

A very rare and obscure cause of rectal haemorrhage is a peptic ulcer in a Meckel's diverticulum.

A few years ago a girl aged 15 was sent to me from South Africa for treatment. The history was that since the age of

6 she had been liable to sudden and very severe haemorrhages from the rectum. In three of the attacks she had nearly died, and on five occasions it had been necessary to give transfusions. Beyond the bleeding there were no symptoms at all. Most careful examination and x-ray investigation had entirely failed to reveal any cause for the condition, and except for a secondary anaemia her blood picture was normal. I was quite unable to make a diagnosis, and finally decided to explore her abdomen. I then discovered a Meckel's diverticulum five inches long with a peptic ulcer at the end of it. I removed this, and since then she has had no further bleeding.

Cobb (1936) collected 100 cases of peptic ulcer in a Meckel's diverticulum. Of these, seventy one had haemorrhage, and in nearly half the cases there was no other symptom. In cases where there are repeated attacks of profuse rectal haemorrhage, especially in young persons, the presence of a peptic ulcer in a Meckel's diverticulum should be suspected. It is usually impossible to demonstrate the diverticulum by radiographs, but this was achieved in one of the cases described by Cobb.

#### Angioma of the Rectum or Sigmoid

This curious condition is congenital, and resembles a cirroid aneurysm of the skin or a cavernous naevus. The wall of the rectum and colon is occupied by a mass of huge blood vessels just beneath the mucous membrane. These enlarged vessels may be arteries or veins, or a combination of both.

In a case which I have under my care at the present time some of the vessels when looked at through the sigmoidoscope are as large as the aorta, and can be seen pulsating. The angioma in this patient starts about four and a half inches up the rectum and extends for fifteen inches almost to the descending colon. This patient had to have an abdominal section, and I thus had the opportunity of examining the bowel from the abdominal aspect. The engorged blood vessels in the affected portion of the colon made the tissue quite firm and stiff, like erectile tissue and this applied also to the mesentery, which consisted of masses of enormous blood vessels.

This patient is now over 60 years of age, but all his life he has suffered from occasional severe haemorrhages.

There are some twelve of such cases on record, and most of them resulted in death from bleeding. One patient, whom I attended for some years, eventually died in Paris from a sudden severe haemorrhage. The condition is not one which lends itself to surgical treatment. The great size and number of the feeding vessels preclude the possibility of excising the affected portion of bowel.

#### Local Injury

A few years ago I was consulted by a lady, 60 years of age, who had a sudden rectal haemorrhage while in apparently good health. During the following twelve hours the bleeding was continuous and she lost over two pints of blood. On examination nothing could be found, except that the lower bowel was full of blood clots and fresh blood was still coming away. The patient was put to bed and treated with cold rectal douches containing hazeline and the administration of morphine. This stopped the bleeding, or at any rate considerably diminished it and next day after washing out the bowel I was able to make a thorough examination with a sigmoidoscope. I then saw that there was a small cut about a quarter of an inch long in the wall some two and a half inches up the rectum. This cut had partly divided a small artery which could be seen pumping when the clot was removed. The bleeding was stopped by cauterizing the bleeding spot and there was no further trouble.

It subsequently transpired that this lady had swallowed some broken pieces of china a fortnight previously and I have no doubt that a fine chip had cut the mucous membrane.

I have also seen bleeding from the rectum due to injury resulting from a man breaking a shooting stick while out shooting pheasants and impaling himself on the lower broken end. The haemorrhage in this case was much less important than the question of damage to the bladder and peritonum. Although the broken shooting stick had gone into the rectum for six inches or so the peritonum was not injured but the back of the bladder was torn. The patient was fortunate enough to survive this injury.

Haemorrhage from the rectum may of course complicate operations upon the rectum and this I shall refer to again later.

### Ulcerative and Haemorrhagic Colitis

Ulcerative colitis or proctitis may cause serious bleeding but as a rule the septicaemic condition quite overshadows the bleeding. A blood count should always be made from time to time as any considerable degree of anaemia is certain to prejudice the patient's chances of recovery and should be corrected by transfusion.

Haemorrhagic colitis causes very serious bleeding and in this condition the bleeding is the chief symptom. The aetiology of this variety of colitis is still uncertain many people believe it to be a form of ulcerative colitis but in typical cases there is no ulceration and my own opinion is that it resembles pellagra of the skin without its characteristic blood picture. The great majority of the sufferers are young adolescent women in whom the condition appears intermittently often over many years.

One patient of mine who was married and had one child lived in a garden suburb on the outskirts of London. One evening her husband returned home to find a large pool of blood just outside the front door and a trail of blood all along the passage inside the house. He not unnaturally thought that his wife had been seriously injured or even murdered but on reaching the kitchen he found her cooking the dinner. She was standing in a pool of blood but was unaware of the fact.

Although the bleeding in these cases may be very considerable it is seldom really serious and I have never heard of a fatal case. Rest in bed and hypodermic injections of thrombokinase in the shape of haemoplastin or one of the other similar preparations usually soon control the bleeding. Recurrences are common however and until we know more about the aetiology of the condition we can do little to prevent them. It is usual to administer calcium in these cases but there is some doubt about the efficacy of this treatment.

### High Blood Pressure

Bleeding from the rectum may occur in persons with very high blood pressure and may be profuse. The bleeding almost certainly comes from a vein in the rectum or colon that has ruptured. I have seen several such cases where the patient had had a really severe haemorrhage but when subsequently examined with the sigmoidoscope the source of the bleeding could not be determined accurately. In one patient an elderly lady the blood pressure previous to the haemorrhage was as high as 260 mm Hg and there were signs of hardened arteries.

The haemorrhage in such cases is beneficial rather than otherwise and if the cause is known the patient should be treated by occasional venesection when the pressure gets high instead of being allowed to bleed vicariously from the bowel. When a sudden and severe haemorrhage has occurred in an elderly subject this cause should be considered and the blood pressure taken. Naturally after

the haemorrhage the blood pressure will have been considerably reduced so that it is important to ascertain it possible what it was before the haemorrhage.

A case is reported by Elgood (1930) of a woman who had profuse haemorrhage from the rectum resulting from an extra uterine pregnancy having ruptured into the lower end of the colon.

A cause of rectal bleeding which is very uncommon in this country but common enough in Egypt is infection with the parasite *Bilharzia haematobia*. There are two varieties of this parasite in one case the ova perforate into the bladder and cause haematuria but in the other they perforate the rectal mucosa and cause rectal haemorrhage. I have seen two such cases in England. An examination with the sigmoidoscope reveals numerous minute haemorrhagic ulcers in the mucous membrane and if one is fortunate the characteristic parasites can be recovered from scrapings from these ulcers. The only treatment is by means of tartar emetic injections. In Egypt such cases are very common and at times the rectum becomes a mass of granular material.

### Methods of Controlling Rectal Haemorrhage

Haemorrhage from the rectum is a complication which may follow any operation upon the rectum and it happens in about 1 per cent of cases after all such operations. The most common time for a haemorrhage is about the eighth day after operation. It is essential that anyone who is going to look after rectal operation cases should know how to control the bleeding as it always occurs unexpectedly and the necessity for immediate attention will be urgent.

The first thing to do when bleeding of any consequence is noticed is to pass a short piece of rubber tubing about three eighths of an inch in diameter and three or four inches long through the anus. The tube should have a safety-pin or a piece of thread through the outer end to prevent it slipping entirely into the rectum. If the bleeding is coming from some small vessel this simple procedure will generally stop it and if the bleeding is more serious the tube will allow the blood to escape and not accumulate in the rectum. In other words the tube will prevent a concealed haemorrhage. If the bleeding restarts after a few minutes it is clear that it is not under proper control and the surgeon should proceed to pack the lower end of the rectum. As a rule this can quite well be managed without an anaesthetic if done by the following method. A piece of rubber tube about six inches long and three eighths of an inch in diameter is taken and a thin strip of dry gauze about an inch wide is wrapped tightly round one end in a figure of 8 so as to form a bulge. This should be just small enough to be pushed through a tubular speculum. The speculum is well greased and is passed into the rectum. The tube with the bulge at one end is then pushed through the speculum until the bulge is above the speculum and the latter can be removed. The bulge of gauze on the tube will now be in the rectum and the end of the tube protruding from the anus. When the tube has been drawn down as far as it will come a large safety pin is put through it about one inch from the anal opening. A long strip of gauze is then wrapped round the tube outside the anus but inside the safety pin. As the wrapping increases it will tend to pull the gauze bulge on the other end of the tube hard down against the bleeding point and if properly done this will at once stop the bleeding. The plug should be left in place for forty-eight hours the patient being given morphine if he feels much

discomfort Should the bleeding restart it will at once be evident, as fresh blood will come through the tube

Another way to stop bleeding is this Cut off the finger of a rubber glove and after passing the end into the rectum, plug gauze into the open end so as to well distend the closed end inside the rectum To prevent the plug slipping in a safety-pin and a roll of gauze are used outside the anus The tube method is the more satisfactory as the glove finger is apt to tear If a plug such as this fails to control the bleeding the patient should be given an anaesthetic and when all the blood has been douched away the bleeding-point can be looked for with a speculum It is generally very difficult, or impossible, to pick up the vessel satisfactorily, and it is better to plug the rectum properly with a gauze plug and tube of suitable size

## OBSERVATIONS ON THE DYSENTERIC CONDITIONS AMONG EUROPEANS OF CALCUTTA

BY

B P TRIBEDI, M.B.

Professor of Pathology and Bacteriology Medical College,  
 Calcutta Bacteriologist to the Government of Bengal

AND

M N DE, M.B., M R C P

Professor of Clinical Medicine Medical College Calcutta,  
 Physician to the Medical College Hospitals

Acton and Knowles (1928) observed 'Chronic and relapsing dysentery we believe to be matters of very serious concern to the large European business firms in Calcutta Although very few deaths from dysentery occur among them, the disease causes a tremendous amount of sickness in that community, and it is responsible for much invalidation and repeated and often prolonged absence from duty We also believe that dysentery is a very important cause of sickness among the general European community in India' In consideration of the importance of the subject we here record some facts which we have come across during our routine diagnostic laboratory work from 1930 to July, 1937

All the materials for study were obtained from Europeans who were either residents of Calcutta or worked in various commercial firms and Government departments Most of the specimens were collected and sent to us but some of the patients personally attended and passed their stool in the laboratory As a rule the specimens were examined within a reasonably short time of being passed, except when this was not possible owing to unavoidable reasons

### The Careful Examination of Stools

Before giving the details of our observations we would like to make a few remarks about our experiences in the course of these examinations The first thing is with regard to the occurrence of amoeba infection This parasite is sometimes encountered in specimens where the physician has hardly any suspicion of it and in which the appearance of the stool is not in the least suggestive of such infection Some symptoms of dyspepsia, vague

unaccountable pain in the abdomen, occasionally more severe before or during passage of a stool, liquid loose stools without obvious cause, pain in the liver with some degree of enlargement of the organ, a low grade pyrexia of unknown origin, and even loss of flesh and strength, are some of the conditions for which an investigation of the stool had been suggested, and often we were amply rewarded by discovering the parasites in their active vegetative forms Another point we would like to emphasize is the tenacity with which these parasites persist in the alimentary tracts of many persons We had had occasion to follow up some cases in which *Entamoeba histolytica* could be found in the stools at any time during the course of seven years The patients reported that whenever they took a course of treatment they felt better and remained well for some time, but any digestive upset or exposure to chill caused a return of some of the symptoms, and it was at this stage that the parasites always made their appearance We may remark in this connexion that the character of the stool was often misleading These parasites had on many occasions been seen in specimens which could easily have been passed as well formed, hard, and to all intents and purposes perfectly innocent-looking A cursory examination of the material showed nothing, but when the specimen was very carefully inspected tiny shreds of mucus were found on the surface, and these contained a great number of the parasites In the same way the examination of a specimen after the patient had taken a saline purgative was more often attended with positive results It is no doubt well known that delay is frequently responsible for many negative findings, but we would lay particular

# DYSENTERY IN EUROPEANS OF CALCUTTA

THE BRITISH  
MEDICAL JOURNAL

Western countries. He further notes however, that in industrial centres, with their associated overcrowding, there are always a certain number of cases. In Calcutta the Europeans live as a group by themselves, isolated from the general population. The latter are confined to the northern portion of the city, from which the European residential quarters are separated by the office quarters, where people collect only during working hours. In the European quarters the municipal authorities have provided underground dustbins and refuse pits, which are kept covered. With regard to the possible dissemination by flies and to the dysenteric infections coinciding with rainfall our curves of incidence for the dry and the monsoon months tell a different story.

Examination of the chart shows that, with regard to the amoebic infections, the highest peak of course is in August but the incidence in the drier seasons is quite high too, and it will be noted that the other high peaks, excepting those of August and July, occur in the months of February, March, May, and October, all of which are dry periods with the lowest rainfall. On the other hand we find a very low incidence in September, a month which would be expected to provide the highest figures, as it corresponds to the end of the monsoons in Bengal.

With respect to the incidence of bacillary infection the curve in the chart tells the same story—namely, that the highest incidence does not always follow the periods with the highest rainfall. The highest peak is in April and the next highest is in January. So, taking all these factors into consideration we might reasonably conclude that the incidence of dysenteric conditions among Europeans in Calcutta does not strictly follow any seasonal variations. Rogers's (1921) figures were from the jail population in India, mainly composed of Indians, with a negligible European element in it, so that the conditions which are responsible for dysentery in the Indian community need not necessarily be the same as with the material we are reviewing.

The people now under consideration were Europeans employed in various commercial and business houses in Calcutta and their families, and resident in that city for fairly long periods. Some of them, of course, go out of the city in their various business pursuits, but we understand that these out-of-station journeys are very few and far between, and for practical purposes they do not alter the conditions.

TABLE III—Showing Sex Incidence and Age Groups

	Amoebic	Bacillary
Children	6	30
Adult Male	96	100
Adult Female	42	102

It is evident from Table III that the number of cases of dysentery in males is not so much in excess as to suggest infection from outside-station areas. It is to be noted, however, that the male population is double that of the female.

It appears from Table II and the chart that the prevalence of the infection is more or less constant with very slight periodic rise and fall, but quite unlike an epidemic curve so it may be supposed that the factors responsible for this disease are constantly present somewhere. It is however needless to point out that if the source could be traced it would go a long way to solve the problem.

From the curative point of view amoebic infection is extremely hard to deal with. The cure of cases of chronic bacillary dysentery is also far from satisfactory. If any light, therefore, could be thrown on the method by which dysenteries spread among the Europeans in Calcutta we might cut the chain of events and thereby arrive at a solution of the problem, moreover, the data thus obtained might be of use in solving the dysentery problem of the country as a whole. *B. melitensis* infection in Malta is a familiar example. When the mode of spread was discovered that disease was stamped out in very little time. Similarly with tuberculosis infection in Western countries by severing the chain of events in the dissemination of the disease this has been brought well under control.

With the same object in view it appeared to us that, taking into consideration the constant prevalence of the infection, the comparatively isolated position of the community, and their standard of life, the personal element—namely, carriers—came uppermost, and that the most likely human factor might be found among the Indian servants and cooks. Another possibility was the green unboiled foodstuff. This latter point required investigation, and we began by periodically collecting green food stuffs from the markets which supply the Europeans here to see if they were dipped in potassium permanganate solution before they are put on the table, but this is never strictly adhered to. That there are carriers among the servants is a very strong possibility, and the scanty evidence that we have been able to collect points towards this conclusion. It appears, from the report of the medical officers attached to the business houses, that cases of dysentery do occur in certain families, and several of them suffer, one after another. Moreover, the worst instances are found in office messes and chummers, where those who are ill invariably contract the same type of infection. Our own endeavour was to investigate the possibility of carriers being present in such isolated foci of infected places, and the few cases we have been able to examine from this angle lend support to this hypothesis.

Before concluding we would like to make a few observations. Acton and Knowles (1928) found the same preponderance of the bacillary infection, and especially the Flexner type, as we encountered. We have included *Ps. pyocyanea*, *Bact. morganii*, *B. carolinus*, and *B. faecalis* in our observations because there are good reasons for believing that they might cause intestinal disorder. In Table I, under the heading "non dysenteric," we have included those cases in which there was no evidence to indicate any abnormal condition of the intestinal tract. Under the heading "non specific" will be found those cases which gave a definite indication of abnormalities of the bowels—namely, mucus, cellular exudate, etc.—but we failed to isolate any of the bacteria included in the chart or any of the amoebae. The association of Charcot-Leyden crystals with amoebiasis seems to be slight, the positive cases of amoebiasis in our series being only 0.8 per cent. In certain cultural examinations of faeces we had the curious experience of seeing a sterile plate even on seventy-two hours' incubation with MacConkey's and bromeresol media, naturally the question of faulty technique arose, but on repeated cultural examinations of other samples from the same patients similar results were obtained. Whether it was due to the presence of a lytic enzyme or an abnormal alteration in the pH of the faeces, or was due to some other factor, we are as yet quite undecided.

### Summary and Conclusion

1 Analyses of 1370 specimens of stools from Europeans resident in Calcutta are recorded

2 The incidence of dysenteric condition—amoebic and bacillary—is noted

3 Possible sources of infection are discussed the probable disseminators seemed to be carriers among the Indian menial staff

4 Although among the Indian population there is a definite seasonal correlation with the disease this was not found to be so in the case of the Calcutta Europeans

5 The association of Charcot-Leyden crystals with amoebiasis could not be found to extend far

Finally we express our grateful thanks to Colonel Vere Hodge professor of medicine Calcutta Medical College Dr G Brandon and his colleagues Drs M C O'Connor and A D Pegg of 21/2 Harrington Street and Lieutenant Colonel A Denham White late civil surgeon of 24 Parganas Bengal for helping us in our work our thanks are also due to the staff of the Pathology Department Medical College Calcutta for giving us every help and to the Director of the All India Institute of Hygiene for supplying us with the numbers of the European population in Calcutta

## PREVENTION OF MEASLES IN A CHILDREN'S HOSPITAL

BY

W E CROSSBIE, M B, B Ch, D P H

Medical Superintendent Alder Hey and Olive Mount Children's Hospitals Liverpool

Measles should no longer be considered a minor infection. It is a major illness causing a considerable mortality and a much greater morbidity among young children affected by it.

The occurrence of measles in a children's ward is a catastrophe as children already ill are exposed to the risk of a second serious illness which they may not be able to overcome. Moreover such an occurrence dislocates the work of the ward and impairs the utility of the hospital. Every effort should therefore be made to prevent the entry of measles into a children's hospital and to check its spread once it has appeared. These objects can best be attained by the system of nursing children in cubicles as by this means it is possible to avoid one child infecting another. In the absence of cubicles the problem which all too often presents itself is how to prevent the disease from spreading among or alternatively to modify its virulence in the children already exposed. In the light of our present knowledge the only measures available are the passive immunization of contacts by one of the following substances (a) serum from patients convalescing from measles (b) serum from adults who have had measles (c) an immune substance (immune

globulin) obtained from the placenta of women who have had measles. Another method sometimes used is to inject whole blood taken from the parents.

During the past winter a considerable number of cases of measles arose in the wards of Alder Hey and Olive Mount Hospitals with the result that it was necessary to immunize many contacts. The substances used for the purpose were (1) serum from adults who have had measles and (2) immune globulin from placental exudate in varying doses. All susceptible contacts were given an immunizing dose as soon as a case of measles was diagnosed in the ward. In practice this meant on the appearance of the rash and there were possibly on the third or fourth day of exposure. The results are tabulated below.

Table showing Results of Immunization with Adult Human Serum and Immune Globulin

Substance used for Immunization	Number of Children					Remarks
	11-15 Days	1-10 Days	0-10 Days	1-10 Days	1-10 Days	
Adult human serum 15 c.c.	1	1	0	13	1	(a) 1 case not immunized (b) 1 case not immunized (c) 1 case not immunized
Placental extract 10 c.c.	0	10	2 (5)	0	0	(b) 1 case not immunized (c) 1 case not immunized
Placental extract 6 c.c.	6	4	9 (1)	19	0	(a) 1 case not immunized (b) 1 case not immunized (c) 1 case not immunized
Placental extract 4 c.c.	12	10	6 (4)	0 (e)	0	(d) 1 case not immunized (e) 1 case not immunized

In assessing the results no attempt has been made to work out a percentage of immunity as in my opinion this tends to convey an impression which may be on the optimistic side. For example one may immunize 100 children and of these only twenty may contract the disease. It is impossible in hospital practice to say with certainty that any or all of the remaining eighty children were actually infected. It is however reasonable to assume that on the average the risk of infection is the same in any one hospital and it is on this basis that comparison should be made.

It will be seen from the above table that the best results were obtained from the use of a 15 c.c. dose of adult human serum or 10 c.c. of immune globulin. Smaller doses of immune globulin did not give the same degree of protection and of the forty-eight children receiving 4 c.c. of that substance twelve did not obtain sufficient immunity to modify the course of the disease. It must be stated here however that no complications or sequelae occurred in these twelve children.

One effect of passive immunization against measles is this method is the prolongation of the incubation period. This is important when quarantining such immunized contacts because one should wait for a certain number of days before admitting other susceptible children to the ward. In considering the cases which developed measles after a period of twenty-one days following the immunization it should be borne in mind that some of these were exposed a second time through contact with children developing a modified form of the disease. We therefore

must face the fact that a child may not be protected against measles even if he has been immunized twelve to fourteen days previous to exposure to infection

As it was thought that the age of the children might have some influence on the results obtained these results were classified as follows

Age	Number Immunized	Number Developing Measles
0-1 year	44	14
1-2 years	88	28
2-3	52	27
3-4	33	12
4-5	19	8
5-6	14	7
Over 6	39	4

Consideration of this table would suggest that the dosage of human serum or immune globulin should not be influenced by age, and that children between 1 and 5 years require a full immunizing dose

While making this investigation it was noticed that the rate of infection tended to be higher in those wards which contained a greater number of children between the ages of 1 and 5 years, although these small children were separated so far as possible and confined to bed in order to avoid intimate contact. It was also noticed that the secondary cases were not always those nearest to the original case. To my mind this suggests that in hospital practice droplet infection is not the sole means by which the infective material is carried from one patient to another, but that the nurses' hands may also be an important medium of conveyance.

A further point of interest to those connected with children's hospitals may lie in the fact that it was not necessary to shut a ward which had become infected with measles. The procedure followed was to remove the case of measles, immunize all susceptible contacts, and use the ward for admission of all cases (preferably older children) who had had the disease previous to admission. Another method employed when more than one ward was infected was to concentrate susceptible and immunized contacts in a single ward, thus freeing the others for 'clean' cases. A third procedure found to be of advantage was to transfer to vacant beds in the infected ward those older children in other wards who had had measles. By these means beds were vacated in clean wards and the hospital could be used to its fullest capacity.

#### Summary and Conclusion

1 From an analysis of different methods of passively immunizing susceptible contacts against measles it is found that the best results are obtained by using the larger doses of immune globulin.

2 Fifteen cubic centimetres of human adult serum and 10 ccm of immune globulin gave approximately the same results.

3 Four cubic centimetres of immune globulin did not modify the disease in some cases.

4 Young children require as large a dose as older children (perhaps larger).

5 Some suggestions are made for the judicious use of beds in infected wards so that the work of the hospital as a whole may not be seriously dislocated.

6 It is suggested that in hospital practice infective material may be conveyed from patient to patient by means other than direct droplet infection.

Finally, no reactions were noted following the injection of immune globulin or human serum.

## Clinical Memoranda

### Tetanus Supervening on Middle-Ear Disease

The following case appears to afford a parallel to that reported in the *Journal* of February 19 by Captain F V Stonham, I.M.S. In his case there was evidence of the introduction of a potentially tetanus-infected medium—namely, dried scum from a stream or dirty powdered cuttlefish—into the discharging meatus. In this case there is no such evidence, but there is direct evidence of an acute exacerbation of chronic otitis media within the incubation period of tetanus, suggesting strongly that the middle ear was the open wound through which accidental infection gained entrance.

#### CASE REPORT

An actress, aged 22, touring small provincial towns in a family troupe, had a history of chronic intermittent discharge from the left ear since childhood. About January 20, 1938—fourteen days before admission to hospital—her left ear became painful and tender. Relief was experienced when a purulent discharge occurred a day or two later. With instillations of hydrogen peroxide the discharge diminished considerably. On January 31 her jaw became stiff, and her dentist, suspecting an impacted molar, removed two molar teeth on the left side. As trismus did not lessen she was referred to Mr C J Macauley, surgeon to this hospital, as a case of tetanus or possibly left-sided parotid abscess.

At 1 p.m. on February 3 she was admitted to this hospital. Temperature 100.6° F, pulse 80, respirations 20. No history of wound or abrasion during the previous three months. Patient lay rather rigidly on her back, but was able to sit up with a little help. Trismus did not allow of the teeth being separated more than half an inch. Neck rigidity present. Spinal, abdominal, and limb muscles showed some hypermetrism, not amounting to rigidity. Tendon reflexes were exaggerated. There were no abnormal eye signs. Palpation of the left mastoid region caused the patient to wince with pain. Tympanic perforation and slight purulent discharge noted.

Consultation with Mr P Dempsey, otologist to the hospital, confirmed the diagnosis of acute suppurative otitis media, and ruled out mastoid involvement or intracranial spread. Trismus and general rigidity increased during the following day, risus sardonicus was noted, and swallowing became somewhat difficult.

Treatment consisted in administration of serum to a total of 140,000 units by the intramuscular route over the first four days. Sodium luminal, 3 grains in 1 ccm, was used twice or thrice daily to prevent spasm, relax rigidity, and secure sleep. The disease ran a relatively mild course and showed definite improvement, until on February 8 signs of bronchopneumonia appeared. The case was transferred to the care of Dr E T Freeman, but despite treatment, which included the free use of an oxygen tent, death supervened on February 12, nine days after admission, from bronchopneumonia and cardiac failure.

#### COMMENTARY

A case of tetanus is reported in which the occurrence of an exacerbation of otitis media during the probable period of infection was a definite feature. In the absence of any other obvious route of infection that of the middle ear must be considered as a probable one. Efforts to establish something more than mere coincidence in this combination may well explain some of the 'idiopathic' cases of tetanus.

I beg to thank Mr C J Macauley for his permission to publish this note.

## ST THOMAS'S REPORTS

*St Thomas's Hospital Reports* Edited by O L V S De Wesselow C Max Page assisted by N R Barrett J St C Elkington A J Wrigley Second Series Vol II (Pp 271 illustrated 10s) London St Thomas's Hospital 1937

The second volume of the new series of *St Thomas's Hospital Reports* contains an interesting and instructive group of articles. Dr Letheby Tidy's monograph on glandular fever and infectious mononucleosis traces the history of the recognition of this disease which even now is liable to be overlooked though occurring sporadically and in mild epidemics in this country. It is possible to differentiate three clinical types of glandular fever: first the original form described by Pfeiffer in which after slight discomfort in swallowing and complaint of sore throat, the cervical glands rapidly enlarge usually to subside in a few days; a second rarer type (monocytic angina) in which after a more prolonged onset the fauces are covered with a membrane indistinguishable in appearance from that of diphtheria and again the cervical glands are much enlarged; a third more prolonged febrile type appears with headache and constitutional disturbance often with eruptions the commonest being erythematous maculo-papular or rubelliform. The blood changes are interesting and occur in all these types. After an initial polynucleosis there is a reaction of the mononuclear tissues resulting in an increase of lymphocytes and monocytes. For diagnosis as well as the blood picture the presence of (heterophile) antibodies in the patient's serum which agglutinate and haemolyse sheep's red cells is almost pathognomonic. The prognosis in all types is good.

Dr Hebert reviewing the progress of anti-tuberculosis work during the last fifteen years points to the more rapid and certain recognition of early cases with the help of x-rays the more accurate estimation of the character and extent of the disease the better arrangements for treatment, especially with collapse and surgical treatment when pneumothorax is ineffective and the increased help afforded by general practitioners to the tuberculosis officer. Apart from the discovery of a cure the chief need appears to be some means of estimating the patient's resisting power to tuberculosis. Dr Tchaperoff believes that primary cancer of the lung is on the increase. Pain in the chest cough dyspnoea and haemoptysis in an elderly person should lead to radiological investigation and possibly bronchoscopy. The method of treatment for most cases is with x-rays though in the majority this is only palliative.

Dr Hearn discussing the diet and treatment of peptic ulcer points out that the possible defects of the strict diet-alkali regime are alkalosis iron deficiency vitamin C deficiency and a low total caloric intake. Alkalosis has been widely discussed, it is probably not common and should be recognizable. Alkali therapy may however interfere with the absorption of iron. A strict ulcer diet may be deficient in vitamin C and it continued long the patient may show scorbutic symptoms the monotony and restrictions may induce states of subnutrition. On the whole the rest-diet-alkali regime appears to be more satisfactory in the medical treatment of peptic ulcer than the high caloric diet of Meulengracht provided sufficient vitamins are added in the form of orange juice and

marmite and adequate iron if there is anaemia. Commenting on the factors influencing the mortality of perforating peptic ulcers of which cases one in four admitted to hospital is fatal Mr Boggon finds the risk rises after twelve hours of perforation ulcers high up on the lesser curvature are specially lethal and patients over fifty years of age do badly. Improvement or results will follow earlier diagnosis and more rapid admission to hospital and careful pre-operative preparation and anaesthesia. The methods of preparing these and other patients for operation are discussed from the anaesthetist's point of view by Dr H B Wilson and Dr Nesworth pleads for more care in keeping anaesthetic records especially for assessing the various factors in post-operative morbidty. Gastro-enterostomy though less often performed than formerly had clearly defined indications. A serious complication is secondary gastro-jejunal ulceration which Mr Romanis points out may occur in two distinct positions—gastro-jejunal at the site of anastomosis closely related to the mesocolon which it may invade and lead to gastro-jejuno-colic fistula and jejunal less common but more likely to perforate into the general peritoneal cavity. Medical treatment with rest dieting and alkali often avails but in most cases a radical operation has to be faced one which will tax the skill and ingenuity of the surgeon.

Mr Kilner deals in detail with the delicate and often remarkably successful technique of cleft lip and palate repair. Dr Jewesbury and Mr Max Page review the pre-operative treatment operative technique and post-operative management of congenital hypertrophic pyloric stenosis. The operative mortality of just over three hundred cases was 12½ per cent. Comparing the results of twenty years figures on cases of carcinoma of the breast operated on in the hospital Messrs Mitchiner Bailey and Price found the mortality practically the same whether the Halstead radical operation or a much more conservative removal of the breast had been performed and urge that this conservative and much less mutilating operation should be more generally adopted in all cases combined with post-operative radiation. Other surgical papers include the treatment of otosclerosis by labyrinthectomy often with remarkable immediate result and the management of imperfect descent of the testis. A follow up of patients operated on for femoral hernia showed a recurrence rate of at least 9 per cent. Dr Goadby describes the surgical treatment adopted in cases of Graves's disease operation is the quickest and most efficient method of relieving the patient's distress while a cure rate of 40 per cent and an 88 per cent chance of sufficient improvement to lead a normal life again are offered by a judicious combination of medical and surgical treatment in this often serious disease. Dr Anwyl Davies has used gonococcus antitoxin with encouraging results when combined with satisfactory drainage and sulphamidamide in the treatment of gonorrhoea. Dr Bowes in a critical review discusses the investigation and treatment of sterility. Cases may be considered absolutely in type when gross defect of uterus or adnexa is present or the tubes are demonstrated to be sealed off completely. Probably not more than 20 per cent of cases of sterility are of such type. Tubal occlusion is an overrated cause since 12 per cent of cases only are irreparable and another 21 per cent have spasm or incomplete occlusion—one third of the cases in all in another third genital hypoplasia is found and in 20 per cent the male is responsible. Much information can be gained from examination of the penile and endometrial smears. Dr Prosser Thomas gives a useful account of occupational

dermatitis, for various reasons there is a poor prognosis. Dr. Oliver concludes from his own work and his survey of the literature that modifications of the Bendien test are of little or no value for the diagnosis of cancer. The volume contains articles on these and other diverse subjects and is well worth study.

### ACTINOMYCOSIS

*Actinomyco-sis*. By Zachary Cope B.A. M.D. M.S., F.R.C.S. (Pp. 248. 52 figures. 8 coloured plates including 1 frontispiece. 15s. net.) London: New York and Toronto: Oxford University Press, 1938.

This monograph deals with a disease which is not very common but which is of very great interest both from biological and from clinical standpoints. It is widely scattered over the whole world, and about sixty cases in man occur in the United Kingdom annually. Among cattle it is far more common, and is, in fact, a disease of considerable importance. After many difficulties arising from the almost universal presence in the lesions of ordinary pyogenic bacteria, the organism was finally established by Homer Wright in 1905 as the actinomycotic fungus.

After a historical introduction and a discussion of the biological incidence and aetiology of the disease, Mr. Zachary Cope passes on to a close study of its clinical pathology and features. Its technical characters are discussed in the many regions in which it appears, such as the tongue, the abdominal cavity, the genito-urinary tract, the liver, and the thorax. There follow examples of its appearance in the skin, in the bones and joints, and in the central nervous system. The treatment of the disease is discussed in detail, and the difficulties which it presents may be realized from the large number of apparently unrelated drugs which have been tried. Potassium iodide in large doses is, of course, the traditional remedy, but Chitty's method of giving comparatively small doses of iodine in milk would seem to be quite as effective, and to present great advantages. Various vaccines and even tuberculin have been tried, but with uncertain results. Where the whole focus can be removed by surgery, this would seem to be the best method of treatment, but it is rarely possible.

The book is beautifully illustrated with both black-and-white and coloured drawings, which one suspects to be from the author's own hand. He is to be congratulated on a most attractive monograph, which sets out clearly all that is known about a most interesting disease.

### MICROSCOPY

*The Microscope: Theory and Practice*. By Conrad Beck, C.B.E. (Pp. 264. 217 figures. 7s. 6d. net.) London: R. and J. Beck Limited, 1938.

*Handbook of Microscopical Technique for Workers in Animal and Plant Tissues*. Edited by C. E. McClung, Ph.D. Second edition revised and enlarged. (Pp. 698. 82 figures. 42s. net.) London: Humphrey Milford, Oxford University Press, 1937.

The little book entitled *The Microscope* will be useful to the practical microscopist and to students of microscopical technique. The author is Mr. Conrad Beck, a member of the firm R. J. Beck, the long-established makers of microscopes. The aim of the book has been to explain "the theory and use of the instrument without reference to mathematics and without scientific details that, although necessary for the designer, are not required for its use." In this the author has in part been successful, though mathematics and scientific details have not been entirely

eliminated. To medical readers the book will make no appeal, the amateur-microscopist will be able to renew his acquaintance with the science of optics, and will find much of interest in the account of refraction, illumination including polarized light, dark-ground illumination, testing of lenses, and various forms of microscope stands and accessory microscope fittings.

*Handbook of Microscopical Technique* is a second edition, and its appearance is justified by the surprising statement that the first has been exhausted. The book is a compilation by many contributors, edited by Professor McClung, Director of Zoological Laboratories, University of Pennsylvania, who claims that this edition has been enlarged by 200 pages up to 700 pages. The volume contains a large amount of information, which is unfortunately embedded deeply in a medium of redundant verbosity—naïve platitudes and superfluities—for example, "a machine called a microtome." It purports to be a 'handbook' for workers in animal and plant tissues. It would certainly not appeal to medical students. It is difficult to conceive that any technician would use it. The chief object of the editor was apparently to make a big book and to use ten words where two words would serve. The book could not be described as a handbook. The reader cannot hold it while reading, and needs the help of a bookrest. Many of the illustrations are unnecessary and help to account for the use of "surface" paper, which contributes to the weight (4 lb. 6 oz.) of the volume.

### BIOCHEMISTRY, ACADEMIC AND APPLIED

*Biological and Clinical Chemistry*. By Matthew Steel, Ph.D. (Pp. 770, illustrated. 36s. net.) London: Henry Kimpton, 1937.

The author of this fairly large work is frankly sanguine in his outlook upon the future developments of his subject, for in his introduction he commits himself to the following view:

"In the not far distant future the subject of biochemistry will show the same degree of development as has been attained in the realm of organic chemistry. When this is the case the composition of protoplasm and the factors that control its production will be as clear as the structure and properties of a simple organic compound. The same will hold true regarding the causes of our bodily ills and the treatment of disease will be as sure and certain as the neutralization of sodium hydroxide by hydrochloric acid."

After this flight of imagination he settles down to produce a book of considerable merit. In so far as the title may be slightly misleading, the relation of the book to clinical chemistry should be first explained, for it is intended for students in their pre-clinical years, and only a relatively small part is devoted to what is normally understood by that subject. Those sections which impinge upon clinical medicine really constitute only an approach to the clinical applications of biochemistry, and rely rather upon the study of normal or physiological material than upon the pathological. However, there is no doubt as to the essential soundness of the idea of linking up at an early stage the academic and applied sections of the subject, and this blend of the two is an important feature of the work.

In other fields, apart from a chapter on the vitamins which is excellent in regard to its carefully designed practical tests, the best chapters are those dealing with the physical chemistry and biophysics of cells and tissues, though that on hydrogen ion concentration is marred by misprints in some of the formulae, and in another place the reader is suddenly confronted with formidable terms

—as for example specific inductance capacity—which demand but do not receive preliminary explanation. The main defect of the book is that it has evidently been published without very careful revision for minor errors are all too frequent and may prove at times disconcerting to those for whom it is written.

## AGRANULOCYTOSIS

*Clinical and Experimental Investigations in Agranulocytosis With Special Reference to the Etiology* By Preben Plum (Pp 410 125 figures) London H K Lewis and Co Ltd Copenhagen Arnold Busch 1937

This report by Dr P Plum of Copenhagen is the most important monograph that has yet appeared on agranulocytosis. It is based on some ninety cases thirty six necropsies with microscopical examination in nineteen and 422 references to the literature. Although credible accounts of agranulocytosis can be traced back to the first years of this century the onset of the recent epidemic was in 1922 when Schultz reported five cases. After 1928 the incidence of the disease increased rapidly reaching a maximum in 1934 and falling off considerably in the next two years. The discovery that most cases of agranulocytosis were associated with the ingestion of amidopyrine came in 1933. There is a striking parallel between the ascending curves for the incidence of agranulocytosis and for the sale of amidopyrine and an equally striking parallelism between the fall of both as soon as the leucotoxic propensity of amidopyrine became generally known.

We owe much of our knowledge of the disease to Plum and he has now provided an able account of the history occurrence clinical picture pathology aetiology diagnosis prognosis and treatment of agranulocytosis. A year or so ago we should have been prepared to accept this as a funeral oration on a serious but interesting disease but the emergence of the sulphonamide group of drugs opens new possibilities for a variety of medicinal diseases including agranulocytosis.

## Notes on Books

The little book entitled *Milestones in Medicine* (London and New York D Appleton Century Company 7s 6d) is as its subtitle indicates a series of lectures delivered at the New York Academy of Medicine in 1936-7 by various eminent authorities. The introduction is supplied by Dr James Alexander Miller president of the Academy and the lectures are by Smith Ely Jelliffe on the Historical Background of Psychiatry Charles R Stockard on the Mechanisms of Heredity Karl Vogel on Medicine at Sea in Days of Sail Frederick Tilney on the Evolution of the Human Brain Henry S Sigerist on the History of Medical History Newton E Wayson on the History of Leprosy and Walter Timme on the Story of the Glands of Internal Secretion.

That a third edition of Dr H M TRAQUIR'S monograph on *Clinical Perimetry* (Kimpton 30s) should have been called for within eleven years is a gratifying sign of the recognition by others than ophthalmologists of the value of perimetry—an achievement largely due to the author's own efforts for as Mr Norman M Dott reminds readers in the foreword to the present edition Dr Traquair has been insistent that the function of vision is equally deserving of study by neurologists as are those of motion and sensation. A book like the present which has become recognized as the standard publication on the subject calls for no commendation from a reviewer. It is only necessary to point out that Dr Traquair has utilized the opportunity of a new edition to add the newer work

on the subject though on some of the aspects one would have liked a rather fuller discussion. The subject of optic aspheric arachnoiditis is worthy of more than the isolated sentence it has been given although the completeness of the book is well illustrated by the fact that the two most significant references to the subject are given in this one sentence. Another minor point to which attention may perhaps be drawn is the fact that in the excellent bibliography the names of authors are sometimes given with initials and more frequently not. In a book of the standing of *Clinical Perimetry* this is almost a major offence.

*Harlow Brooks Man and Doctor* by JOHN J MOOREHEAD M.D. is published in this country by Hamilton Hamilton at 10s 6d. Harlow Brooks was related to as H B is said to have made in his young days the best damned autopsy in New York City a story what remarkable testimonial. Starting in New York in 1895 Brooks became in twenty years one of the most popular physicians in that city and was especially interested in cardiovascular disease as shown by the bibliography of his seven or four publications. He had enormous energy a human dynamo and would take any amount of trouble for his patients and friends and is described as literally a one man social service organization. Outspoken and kindly he had a full life was spoken of as the perfect patient and his biographer says no man in our day and generation so nearly filled the position of the renowned Osier—very high praise. Harlow Brooks died in a hospital after he had been instrumental in founding and opening a suppurative pyelophlebitis which he practically died for himself. The book is a labour of love of a contemporary.

## Preparations and Appliances

### A NEW CHLORINE ANTISEPTIC

Azochloramid (Wallace and Tiernan Ltd, Power Road, Gunnersbury, W.) is an antiseptic with the chemical title of N N dichloroazodicarbonamide. The manufacturers claim that it represents an advance on chloramine T in that it is considerably more stable in contact with exudate and its bactericidal action is relatively slow but is particularly non-selective. A concentration of 1 in 1000 is sufficient for the presence of horse serum desfero bacteria and is also effective against anaerobic Gram positive or Gram negative. The compound is non-irritant to the skin on exposure to air. It is soluble in an oily solution (1 in 100 in ether) and also in a concentrated saline solution which when diluted up to 1 in 1000 gives a 1 in 3000 solution in 1000 c.c. of water. Azochloramid has been tested in several clinics and the favourable reports have been published regarding its action on infected wounds.

The war provided a unique experience in the treatment of infected wounds and the value of the hypochlorite and chloramine was fully proved. Certain disadvantages and inconveniences attending their use have limited the popularity of these substances in civil practice. The new chlorine compound appears to prevent important disadvantages—namely stability, duration of action and non-irritancy and hence represents an interesting advance in therapeutic practice.

### A LAXATIVE ANTACID

Entacarb powder (Messrs Reed and Carter Ltd) is a mixture of carbonates and bicarbonates of calcium magnesium potassium and bismuth together with a small amount of silicate. The proportions of the various elements are arranged so that the powder has a gentle laxative action. The aim of the mixture is to produce an efficient antacid which does not produce calcium depletion. The preparation is particularly suitable for use in very convenient of a number of patients.

## EPIDEMIC INFLUENZA

Ever since the discovery in 1933 by Smith, Andrewes, and Laidlaw that influenza was caused by a filterable virus the attention of the medical profession has been focused on this field of medical research. This interest is hardly to be wondered at, for with exact knowledge of the aetiology of this disease the possibility of the solution to various contingent problems came at last within our reach. What, for instance, is the aetiology of that collection of infections of the upper respiratory tract which in the past have been labelled "influenza" for want of a better term—are they all due to the same virus? Will it be possible to apply specific prophylaxis to the control of epidemic influenza and what chances are there of preparing a curative serum for this disease? These are probably the more important questions to which answers have been anxiously awaited.

From time to time since the publication of the original paper by the Hampstead workers in 1933 readers of this *Journal* have been informed as to the progress which has been made in influenza research at home and abroad. All are aware of the confirmation of this work, at first by Francis in America in 1930, next year by the British workers themselves, and subsequently by workers in different parts of the world. The virus aetiology of influenza rests on a firm basis. What of the progress which has been made with these other problems? A recently published report to the Medical Research Council by C. H. Stuart-Harris, C. H. Andrewes, and Wilson Smith, together with D. K. M. Chalmers, E. G. H. Cowen and D. L. Hughes,<sup>1</sup> provides an answer to this question. This study of epidemic influenza has special reference to the investigation of the 1936-7 epidemic, and since in reporting their work advances in influenza research abroad are discussed the whole gives an excellent up-to-date account of the influenza problem.

As in previous epidemics, no difficulty was encountered in recovering virus from typical cases, the ferret being employed for the purpose. The announcement by Andrewes, Laidlaw, and Smith and by Francis in America independently in 1934 that the mouse could be infected with ferret-passage

virus led one to hope that this animal might eventually be used instead of the ferret for recovering virus from man. This would have been a great advantage and would have brought this line of work within the reach of practically all laboratories. But although last year Francis and Magill reported having isolated virus direct from man by means of mouse inoculation, it would not appear that for this purpose, the mouse will replace the ferret. The American workers found that a number of passages were necessary before the infection in the mouse became apparent, and Andrewes, Wilson Smith, and Stuart-Harris now report that a few attempts made by them to infect mice directly from man were unsuccessful, though they consider that had they persisted with these experiments, they would without doubt have obtained results similar to those of Francis and Magill. The mouse has proved extremely useful for experiments with ferret-passage virus, but it does not seem to be susceptible enough for the isolation of virus direct from human material. The laboratory diagnosis of influenza therefore would still seem to depend on the isolation of virus by ferret inoculation, though Francis in America and Fairbrother over here both find that the complement-fixation reaction is almost as valuable.

In connexion with the strain of virus isolated during the 1936-7 epidemic Andrewes, Wilson Smith, and Stuart-Harris have interesting and important observations to make. It was at one time thought that all strains of influenza virus were the same but this belief was shaken when Magill and Francis reported some eighteen months ago that two strains which they had considered identical could be differentiated by means of antisera made in the rabbit. The British workers now confirm this observation, different serological strains of influenza virus exist. This is rather disappointing, for although these serological strains possess antigens in common, their differences would appear to be sufficiently great to be of importance in attempts at specific prophylaxis. With regard to the question of specific prophylaxis Section VI of this report to the Medical Research Council contains further evidence concerning the immunization of ferrets and mice. The new facts here concern the possibility of immunizing ferrets so that they resist contact infection satisfactorily, and the question of the relation between the level of circulating antibody and degree of immunity. Previous work had suggested that the amount of circulating antibody was a measure of immunity, but Francis and Shope (1936) showed that this was not always so and Wilson Smith, Andrewes and Stuart-Harris now confirm this. They conclude

<sup>1</sup> Medical Research Council. Special Report Series No. 223. A Study of Epidemic Influenza with Special Reference to the 1936-7 Epidemic. H.M. Stationery Office, 1938. (2s. 6d.)

that a high titre of antibody against a given strain indicates a good immunity against that strain but that the converse is not necessarily true. So far as the effective immunization of man is concerned no great advance is reported. It has been shown previously that man can be inoculated subcutaneously with influenza vaccines consisting either of active virus (Francis and Magill) formalized virus (Andrewes and Smith) or heat killed virus (Fairbrother and Hoyle) with the production of little in the way of reactions but with good antibody response. The British workers now report the result of certain experiments designed to test the efficacy of prophylactic immunization. At the time of these trials the existence of a plurality of types of virus was not recognized and unfortunately the vaccinated men were unavoidably exposed to infection too soon after immunization so that the experiments remained inconclusive and we shall have to await further trials before it can be known whether specific prophylaxis is to help us in combating epidemic influenza.

A large section of the report deals with the clinical picture produced by influenza virus in man and its differentiation from other conditions which have gone under the name of influenza. The recovery of virus from the pharynx by ferret inoculation has been relied on in differentiating influenza from other conditions. Several epidemics of respiratory disorders including the 1936-7 influenza epidemic were investigated clinically, epidemiologically and aetiologicaly and from this inquiry Stuart Harris and his colleagues Chalmers and Cowen conclude that influenza is not only an aetiological entity but a clearly distinguishable clinical entity as well. They find no evidence of the existence of gastric and nervous types of influenza and in view of their observation that catarrhal symptoms dominate the picture early in the non-influenzal epidemic respiratory conditions they suggest for these the name of "febrile catarrhs." Admittedly these conclusions may need modification in the light of future observations but Stuart Harris and his colleagues are to be congratulated on what they have achieved. It forms an important contribution to this valuable report.

### STATUS OF THE RADIOTHERAPIST

For some years past it has been evident from reviews and articles which have appeared both in these columns and elsewhere that there are certain difficulties attending the practice of radiotherapy which deserve a thorough and careful investigation. The matter is not one of mere academic interest but is of fundamental and far reaching importance both to the medical profession as a whole and also

indirectly to the general public. The last report of the Radium Commission frankly states that considerable anxiety has been aroused on account of the difficulty in obtaining suitably qualified men and women who are competent to undertake the control of radiotherapeutic departments. In our review of that report<sup>1</sup> two reasons were advanced for this difficulty. The first is an entirely personal one. For its efficient practice radiotherapy demands a very unusual combination of interests for in addition to a thorough and expert knowledge of practical surgery there must be a no less thorough and expert knowledge of the clinical applications of x-rays and radium and of their methods of action. It is now generally recognized that as a preliminary to undertaking special training in radiology the prospective radiotherapist should obtain one of the higher surgical qualifications such as are necessary to qualify for appointment to the honorary surgical staff of one of the large general hospitals. For the successful or even safe practice of radiotherapy itself prolonged and intensive study with routine practical work in a recognized radiotherapeutic department is essential. During this work one of the special diplomas in radiology will be taken which though generally insufficient so far as the therapeutic side of the work is concerned nevertheless assures that the candidate has received some training in the necessary branches of physics. In this connexion the warning issued by the Radium Commission on more than one occasion cannot be too strongly emphasized—namely that radium is not only valueless but dangerous in the absence of knowledge and experience." The same remark is of course equally applicable in the case of x-rays. The problems of dosage and distribution of the radiations are fundamental as regards either success or safety and are themselves dependent upon physical measurements. No rule-of-thumb methods can be laid down each individual case requires specially planned treatment and after-treatment. Such considerations are enough to demonstrate that attendance at a short post-graduate course though interesting as showing the main principles of technique is altogether insufficient for anybody who contemplates the practice of radiotherapy. The use of radium should be rigidly confined to those who have had proper training in its use. Here the following remarks by a surgeon<sup>2</sup> are worthy of quotation.

"It cannot be too strongly asserted that nothing is worse than niggling, meddling, intervening in cancer cases. In every case it should either be thorough treatment by irradiation or thorough treatment by surgery and in many cases it is now a question of the right treatment by radium for the primary focus and thorough

<sup>1</sup> *British Medical Journal*, December 25, 1937, p. 1299.  
<sup>2</sup> G. Grey Turner, M.S., F.R.C.S., Lecturer in Audiology to the Section of Surgery, Royal Society of Medicine, November 1937.

treatment by surgery for the path of probable malignant invasion. Nothing can be worse, and nothing is more wicked, than the attitude which relies on a spot of x rays or a dash of radium, combined perhaps with 'a trifling surgical interference.' Such means of dealing with cancer are nothing short of criminal, and the cases would probably be very much better if they were left alone."

It is evident that special and unusual combinations of professional knowledge and skill are necessary to form an efficient radiotherapist, and therefore that such people will not be easy to find. There is also, however, as indicated in our review of the Commission's report, a second factor which enters largely into the problem. This is the inadequate status accorded to the radiotherapist at certain hospitals. For reasons which we have set forth on previous occasions, radiotherapy cannot be satisfactorily carried out except in institutions where there are ample facilities for laboratory investigation and where the necessary research work can be carried out. As a general rule such a combination will usually be found in connexion with existing hospitals, medical schools, and universities. From the nature of his work the radiotherapist will almost necessarily be a full-time officer. The work is far too dangerous to allow of its being delegated to non-medical assistants, no matter how well trained and experienced they may be. As a consequence of this the radiotherapist must be a salaried officer of the institution, and this appears to be the source of all the trouble as regards his or her status in the hospital. For many years, as the Radium Commission points out, it has been customary to appoint "salaried pathologists who have permission to treat private patients within the hospital. If this latter practice were extended to radiotherapists in charge of centres there would be greater inducement to senior men to take up such appointments." The Commission further strongly emphasizes its recommendation that a radiotherapist should have the status of a member of the honorary staff, should be in effective control of all the radium, and either in charge of or in close association with the x-ray department of the hospital. It is a particularly fortunate thing that much of the radium available for use in our hospitals is national property and that its use is supervised by the Commission and the Medical Research Council, which work in close and harmonious co-operation.

In some cases the expressed views of the Commission are loyally carried out, but in others the conditions of working leave much to be desired. A careful perusal of the last report will show that reference is no longer made to the "radium officer" — a term which in itself was calculated to mark a distinction in status between the radiotherapist and members of the honorary staff. In the past there

were serious misapprehensions as to the nature and scope of the duties involved. Thus in an advertisement inviting applications for the post of "radium officer" which appeared about 1931, one of his duties was "to apply radium under the direction of the honorary staff," and about the same time a surgeon was heard to remark apropos of the same subject, "What I want is somebody to put the radium in for me." These two instances are enough to indicate the difficulties that have had to be contended with. Even at the present time there are institutions where patients who are clearly subjects for radiotherapy have to be admitted under the care of a member of the honorary staff, in whose *nominal* charge they remain during the whole of their stay in hospital. With paying patients the injustice of such arrangements may be accentuated, the bulk of the fees being paid not to the person who has planned and executed the treatment but to the honorary surgeon under whose nominal care the patient has been admitted.

A state of affairs like this is clearly not calculated to attract the type of man or woman who is competent and qualified to undertake radiotherapeutic work, and such being the case it is time that it should be put an end to, before further mischief is done. It is gratifying to note that the Radium Commission not only fully appreciates the difficulties of the situation but has the power to insist upon its recommendations being put into practice. There does not to the average mind appear to be any fundamental distinction between honorary and salaried medical officers of a hospital. The former make their living from their hospital appointment indirectly, the latter directly. As regards the value of the services rendered by either the one or the other, this must always be very largely a personal matter. In the great medical schools there are teachers and research workers holding professorial rank, since the conditions of their appointments render whole-time attendance necessary, they must also be salaried officers, but nobody in his senses would regard them as on that account subordinate to the ordinary members of the visiting staff. With the adaptation of scientific progress to clinical work the number of whole-time workers must increase, and it is only common justice that they should be placed in full control of their various departments. It is perhaps less than a century ago that surgeons were admitted to full equality with physicians, the claim now advanced is that those in control of special departments shall have accorded to them the status and privileges to which their professional qualifications and experience give them an undoubted right. It is in the interest of all concerned that the best brains should be attracted and encouraged to take up the study and practice of

such a subject as radiotherapy where the smallest errors of judgment may have far reaching and disastrous consequences

### MUSCULAR WORK IN GAS-PROTECTIVE CLOTHING

In the recent discussion on the medical organization of air raid precautions at the Royal Society of Medicine (reported on April 23 at p. 910) the point was raised as to the physiological effects of wearing protective clothing. One speaker said that he had seen a number of healthy men taking part in decontamination and anti gas measures who owing to the clothing were unfit to carry on for longer than a few minutes. It has always been obvious that the difficulty and distress produced by any degree of work when carried out in full anti-gas protective clothing were due to incipient heat stroke. The basic factor of this is the combination of rising temperature and saturation by water vapour of the air within the impervious suit. That it would be impossible from the practical standpoint to deal with the situation either by absorption of the moisture or by the mechanical inflow of cool dry air was easy to demonstrate—both have been tried. Attempts to absorb the moisture with calcium chloride produced no effect upon the physiological state of observers clothed in these garments and there was the definite disadvantage that the calcium chloride gets most unpleasantly hot. Attempts have also been made to remove the saturated air by pumping fresh air in at one end of the suit and out at the other but the rate of flow required to produce measurable amelioration is so high as to make the method impracticable. Some important experiments on the control of body temperature and physiological reactions during muscular work in gas-protective clothing have been undertaken by Dr G. P. Crowden of the London School of Hygiene and Tropical Medicine.<sup>1</sup> He discovered first of all that if wet cloths were applied to the outside of the protective oilskin garment the impending heat collapse of the subject was averted and work was able to be resumed. This led him to test the effectiveness of a water-retaining garment of khaki drill worn over the single piece protective suit and in a series of experiments he proved that despite the weight of the additional clothing the increased rate of loss of body heat due to the evaporative cooling of the protective garment was continuous (not a mere temporary sensation as the first experiment might have suggested) and that the subject was able under such conditions to carry on muscular work in a very warm environment without fatigue or discomfort. The feasibility was next explored of bringing the cooling wet surface even closer by giving a wettable external fabric facing to the protective layer—an expedient which has also the advantage of limiting the protective clothing to the one suit. Accordingly a service pattern protective clothing consisting of jacket trousers and hood made

from rubber was faced externally with an absorbent fabric wetted with water. In this apparel the subject was found in even better condition at the end of an equivalent period of work. Such clothing is more easily put on and of looser fit than either the single piece garment of oilskin or the double garment of oilskin and khaki drill but it is considered doubtful whether it would be as effective in its protection against mustard gas because the separate jacket trousers and hood fail to envelop the subject as completely as the single piece.

Dr Crowden's first results were obtained in laboratory experiments on young assistants and were so convincing that it seemed justifiable to make a test of the effectiveness of wetted protective garments under field conditions in warm weather. Accordingly such tests have been carried out at an Officers' Training Corps camp at Svanage and the results have again shown that if the outer surface of the clothing is maintained wet during the performance of muscular work then the accumulation of body heat is prevented, the sweating much reduced, and the risk of heat collapse even under hot summer conditions eliminated. An outer suit of wetted material worn over the oilskin proved effective and the facing of the gas proof material with an outer fabric periodically wetted proved even better in maintaining the heat balance essential for comfort and for the continued performance of muscular work. The men who wore the wet overall's outside the protective outfit or put on the fabric faced rubber suit were apparently no more fatigued than if they had been wearing ordinary clothing permeable to the air. The ingenious incorporation of a water holding layer in the actual fabric of the suit seems as if it might have other advantages. If it could be attached to the oil film coated surface (so far it seems only to have been added to a rubberized material) it might give considerable mechanical protection to the delicate surface. Moreover when wet as it is intended to be it should give added protection against mustard gas because of the relative insolubility of this gas in water and against lewisite because of its relatively rapid hydrolysis. On the other hand it seems doubtful whether when so attached the protective fabric would stand boiling for the prolonged periods necessary for decontamination.

### A STANDARD FOR PREMATURITY

In the course of a periodical revision of the well known clinical report of Queen Charlotte's Maternity Hospital the question of the definition of prematurity came up for discussion. It was decided to refer this matter to the British Paediatric Association and to the Section of the Study of Disease in Childhood of the Royal Society of Medicine. These two bodies nominated a joint committee consisting of Dr Norman Capon, Dr Helen Mackay, Dr Kenneth Tallerman and Dr Alan Moncrieff. After due consideration of the various aspects of the subject this committee suggested a definition based upon a standard of 5½ lb or under and the result of their deliberations was circulated to

various interested bodies including the Royal College of Physicians of London and the British College of Obstetricians and Gynaecologists. Neither of these two organizations was completely satisfied with the wording of the definition, and a joint committee was set up consisting of Sir Ewen Maclean (B C O G), Sir Arthur MacNalty (R C P and Ministry of Health), Professor W W Jameson (R C P), Professor Fletcher Shaw (B C O G), Dr H C Cameron (R C P), Dr Percy Stocks (R C P and General Register Office, Somerset House), Dr Alan Moncrieff (R C P). This committee came to the conclusion that it was impossible to define prematurity in any satisfactory manner, but, with regard to the purposes for which the proposed definition would be used, the committee agreed that some standard was desirable. It therefore put forward a recommendation which was subsequently somewhat modified, and the final proposal reads as follows:

"That in conformity with the standard in international use an infant whose birth-weight is  $5\frac{1}{2}$  lb (approximately 2,500 grammes) or less shall be considered, for the purpose of comparison of records, as either immature or prematurely born, according as the estimated period of gestation is full time or less."

It is hoped that this standard will now be utilized by all maternity institutions, public health authorities, and others concerned with the newborn baby, so that some uniform comparison of results may be possible.

### THE SIR JOHN McFADYEAN FESTSCHRIFT

Fifty years ago the *Journal of Comparative Pathology and Therapeutics* was started as a private venture by Sir John McFadyean, now the octogenarian doyen of the veterinary profession who has since edited it almost single-handed. During its jubilee year the editor was prevailed upon by his colleagues to give them a free hand: they have dedicated the last quarterly number of the *Journal* for 1937 as a jubilee number<sup>1</sup> to the father and editor of the *Journal*. Sir John's long services recall, and it is to be hoped will rival, those of Virchow (1821-1902) whose *Archiv* began in 1847. It is hardly rash to predict that some day the *Journal of Comparative Pathology and Therapeutics* will remind generations to come of its founder by an eponymous title. The tributes in this number of more than 200 pages have been world-wide and are generously illustrated; there are four portraits of Sir John at different dates in his professional career between 1890 and 1937, and twenty-three of his many admirers who here praise a famous man. Among these Sir Robert Muir and Sir John Ledingham are foremost in expressing appreciation of his work on tuberculosis, viruses, infection and immunity, epizootic abortion, foot-and-mouth disease, Johnes disease and nephritis in animals. Other colleagues deal in more detail with the subjects he has advanced and adorned: thus Dr R E Glover of the National Institute for Medical Research, Farm Laboratories, Mill Hill describes his contributions to tubercu-

losis, and Mr L G Wright shows how Sir John has influenced clinical veterinary surgery. Lists of his contributions to his *Journal* and that of the Royal Agricultural Society of England appropriately find a place in this number. Professor G H Wooldridge, now vice-president of the Royal Veterinary College, London, writes with forty years' experience of the greatness of this former Principal and Dean of the College, and the same story is told as pleasantly, but more fully, in the three unsigned articles on "the journal," "the man," and his "disciples."

### TEMPORARY STERILIZATION BY X RAYS

The production of an artificial menopause by irradiation of the ovaries in women approaching the menopausal age has been the subject of numerous reports, so that there is now general agreement as to the indications, dosage, and technique. It is far otherwise when younger women are considered, and a recent paper by Corscaden, Kasabach, and Lenz<sup>1</sup> emphasizes rather than solves the difficulties. Their report deals with fifty-eight patients under the age of 40 who were given what the authors call a "substerilizing dose of radiation." The term is not to be recommended, since if the treatment is successful the patient is in fact rendered sterile, although recovery of ovarian function may occur after an unpredictable interval. In twenty-four cases radium was used. The authors agree that the effect of radium is on the ovaries, as is the case with x-rays, destroying ripe Graafian follicles; they admit also that the dose delivered to the ovaries from intra-uterine radium cannot be estimated with any accuracy greater than  $\pm 50$  per cent, so that these cases cannot be further discussed. In the cases treated by x-rays their results lend strong support to the view generally held in this country that it is very difficult to produce a permanent artificial menopause in young women: for bleeding returned in all but three of their patients within a few months to five years. The problem is, however, a wider one than merely that of dosage. It may be accepted that while a dose of 260 r to the ovaries in a woman over 45, or of 300 r between 40 and 45, will result in a permanent menopause, a dose of even 400 r in a young woman may result in only temporary sterilization. Since the menopausal symptoms in young women are apt to be severe, the only justification for x-ray sterilization is the desire to preserve reproductive function, and the question then arises whether there is any risk of abnormality in the children of mothers who have been thus temporarily sterilized. Although in Corscaden's series there were five abortions and two deaths in infancy out of eleven pregnancies subsequent to x-ray sterilization, the larger collections of cases—for example, the 600 collected by Murphy—have shown that radiotherapy does not lead to foetal abnormalities in subsequent pregnancies. The geneticist, however, has shown that the gene mutations produced by radiations are generally recessive and that abnormal offspring would therefore

<sup>1</sup> *Journal of Comparative Pathology and Therapeutics*, Dec. 1937, pp. 217-246. Jubilee number. A Festschrift to Sir John McFadyean.

<sup>1</sup> *Radiology* 1938, 30, 203.  
<sup>2</sup> *Amer. J. Roentgen* 1929, 22, 207.

appear in the next generation only if two such recessive genes were mated. So long as a ray sterilization of young women is confined to strictly medical indications the probability of marriage between two of their offspring is infinitesimal so that as Waddington states the possibility of an increased mutation rate in so small a group of potential mothers may be considered of minor importance. It must also be remembered that the results of genetic experiments in *Drosophila* may not be directly applicable to man: for example while repeated doses of radiation appear to be arithmetically cumulative for *Drosophila* genes there is no evidence that such is the case in man: indeed the International Protection Regulations allow a dose of 1 r per week and no cumulative effects are known from dosage of this order over periods of many years. Approaching the problem from another aspect Demerec<sup>1</sup> has found that there is a difference in radio sensitivity between the genes of two strains of *Drosophila*. He points out that since gene mutations may occur in somatic cells just as in germ cells such differences in sensitivity would readily explain the differential lethal effect of radiation on various tissues. The lack of evidence of such gene mutations in human tissues may be due to the difficulties of observation and cannot absolve the radiotherapist from caution where germ cells are concerned. Fortunately on purely clinical grounds temporary x-ray sterilization cannot be advised other than in exceptional cases.

### TETANUS FROM A CANCER CURE

From time to time new methods of treating cancer are devised which have a plausible theoretical basis and appear to yield promising initial results, but almost invariably they cause ultimate disappointment. Their first announcement from a reputable source creates a situation of some difficulty both for the would be user and we may add in editorial policy since the available evidence may justify neither approval nor condemnation and the cynicism bred of bitter past experience may just possibly be misapplied. Such an announcement was made in Canada by H. C. Connell in 1935: we drew attention to it in these columns and expressed the opinion that the theoretical basis of the proposed treatment though ingenious required more experimental justification than it had received. In a letter to the *Journal* about the same time Dr W. E. Giv wrote:

We have prepared from mouse tumours in accordance with directions received the solutions which Dr Connell calls 'ensols' and have tested these 'ensols' on the appropriate tumours of mice. In no case has the growth of a tumour been checked or affected in any way. The treatment was based on the action of *Cl. histolyticum* which as its name implies produces a ferment with a solvent action on tissue. It was claimed that when this micro-organism was cultivated in a suspension of a malignant growth it formed lysins

specific for the cells of that growth: this proposition is doubtful and does not appear to have been proved. Nevertheless the method advocated was the lysis by bacterial action of a portion of the patient's own growth and injections of a filtrate of this preparation supposed to contain a lysin which would act upon the remaining growth in the body. It appears that the exigencies of widespread application in America have led to the abandonment of this method of preparing autogenous lysins and a preparation from cancerous tissue whatsoever obtained has been considered efficient for the treatment presumably of similar growths in any patients. It is now reported from the United States that eleven deaths have rapidly followed injections of some of the material and investigation has already made it clear that the batch concerned must have contained tetanus toxin. This was a danger obviously to be feared from such a product. *Cl. histolyticum* and *Cl. tetani* belong to the same genus and grow under the same conditions and contamination of the tissue used could easily lead to such a result. The account given of the conditions under which the product has been manufactured is far from reassuring. Although this disaster has of course no bearing whatever on the possible usefulness of this treatment properly applied and safeguarded it will doubtless and rightly serve as a setback to the indiscriminate application of treatments which have been insufficiently tested and are not under adequate control. The responsibility of anyone who publicly advocates a new method of treating cancer is heavy: one the credulity of despair will rapidly bring many patients to his door. An endless series of melancholy failures on lines which were made at first to appear promising should serve as a warning against accepting new claims of this kind unless they are backed by acknowledged authority.

Dr E. Arnold Carmichael will deliver the Marston Lectures on 'The Study of Reflex Action in the Human Autonomic Nervous System' in the Hall of the Royal College of Physicians of Edinburgh on Thursday and Friday, May 26 and 27 at 5 p.m.

We regret to announce the death of Dr W. H. Maxwell Telling, formerly Professor of Medicine in the University of Leeds and for thirty-two years physician to the General Infirmary at Leeds, and of Mr Percival Furnivall, consulting surgeon to the London Hospital.

*J. Amer. med. Ass.* 1938 110 1133-1134

Dr I. W. Maill, senior anaesthetist to the Westminster Hospital, has been awarded the triennial Human Medal for original work on outstanding mental anaesthesia or in subjects directly connected therewith. The award is made by the Council of the Royal Society of Medicine on the recommendation of the Council of the Section of Anaesthetics.

# SURGICAL PROCEDURES IN GENERAL PRACTICE

*This is one of a series of articles contributed by invitation*

## TREATMENT OF OTITIS MEDIA

BY  
MYLES FORMBY, F.R.C.S.

For the purpose of description and the consideration of treatment inflammatory conditions occurring in the middle ear are conveniently classified as (1) catarrhal, and (2) suppurative. Each variety may be met with in an acute or a chronic form. No sharp line of demarcation exists either clinically or pathologically between these four types of otitis media, but an account of the treatment of a case representative of each provides a suitable means of discussing the subject.

### Acute Catarrhal Otitis Media

This condition is characterized by its sudden onset, pain in the ear, some disturbance of hearing, and pyrexia, and is usually associated with inflammation of the nasopharynx. The diagnosis is determined from the appearance of the tympanic membrane. The external meatus must be thoroughly cleared of wax and debris before an attempt is made to study the condition of the drum. In a typical case the changes seen are a general loss of detail, absence of the cone of light, thickening of the whole membrane, poor outline of the handle of the malleus, and a dilatation of the blood vessels, particularly round the periphery and down the handle of the malleus. The tension and mobility of the drumhead are important and should be tested in every case. This is best carried out by means of Siegle's otoscope which provides a magnification of two dioptries and a ready means of watching the movements of the drum in response to gentle alterations of air pressure in the external auditory meatus. The thickening of the tissues resulting from acute catarrhal inflammation increases tension and diminishes mobility, but the latter is not absent, as it usually is in suppurative otitis media.

The pathological changes which provide the clinical picture of acute catarrhal otitis media may either resolve or progress to suppuration. To aid resolution, general treatment for an acute febrile illness is given and special attention directed to the nasopharynx. Congestion is relieved and drainage facilitated by spraying the nose with 1 per cent ephedrine in normal saline every four hours. Steam inhalations of tinct benzoin or menthol an hour or so after spraying the nose with ephedrine solution are both soothing and beneficial. It is particularly important that the patient be kept warm after having an inhalation.

The discomfort in the ear is relieved by local heat and the oral administration of aspirin. The local heat is best applied by the instillation of warm oily drops, 2 per cent to 5 per cent phenol in glycerin, or sedonan (Napp), into the meatus and by covering the ear and adjacent parts with cotton-wool warmed before a fire, by a hot-water bottle, or by an electric pad if available.

### Acute Suppurative Otitis Media

A most important factor in the management of acute catarrhal otitis media is the keeping of a careful watch for the development of suppurative changes. These are to be suspected where the constitutional symptoms tend to

increase, the temperature remains high, and there is a more rapid pulse rate, with persistence of pain. Repeated examinations of the membrana tympani will reveal the progress of events taking place in the middle ear. The alterations from the normal seen in acute catarrhal otitis media become more pronounced. The dilatation of blood vessels increases, but the reddening of the drum may be obscured by the desquamation of the surface epithelium, which is greyish, by the presence of red or purple haemorrhagic bullae on the drum, or by a collection of yellow pus in the middle ear. If the outer ear is carefully and thoroughly cleansed the meatus at its junction with the tympanic ring, particularly above, will be found to be acutely inflamed. In most cases a part or the whole of the membrane will be bulging into the meatus and gentle compression with a Siegle's speculum will fail to produce any movement. Frequently pressure over the tip of the mastoid process causes pain. When suppuration is present or is suspected in the middle ear adequate drainage must be provided by incision of the tympanic membrane.

### Myringotomy

In itself this is a small operation, but one requiring great care and precision, it should only be attempted with the correct instruments on a patient properly prepared.

*Instruments*—The aural speculum should be the largest that will fit comfortably into the meatus, an electric

FIG 1—Agnew's myringotome

auriscope provides an efficient and suitable illumination, or the usual frontal mirror can be employed, but a good light is essential. There are several suitable patterns of knife, but Agnew's myringotome is probably the most

FIG 2—Siegle's speculum

convenient. The important features are that it should be small enough to pass easily down the speculum and the meatus, have a short blade and a fine point (special care being taken to see that this is not bent) be very sharp, and be capable of being held so that the view of the

drumhead is not obscured. Aural dressing forceps and Siegle's speculum are not essential but are most useful adjuncts.

**Anaesthetic**—No local anesthetic effectively anaesthetizes an acutely inflamed tympanic membrane and general anaesthesia must be employed. Nitrous oxide and oxygen ethyl chloride or intravenous ether are all suitable anaesthetics for this operation if properly administered.

**Preparation**—The patient is prepared for a general anaesthetic the outer ear being cleansed by washing and the application of spirit. The depths of the meatus should be swabbed out with spirit when the patient is anaesthetized.

#### OPERATION

Careful asepsis must be observed. Under direct vision carefully insert the aural speculum into the cartilaginous meatus and identify the drum. Maintaining a good view

FIG 3—Right tympanic membrane showing position of incision

of the field of operation incise the membrane from below upwards throughout its length by means of a slightly curved incision just posterior to the handle of the malleus. The drum is immediately obscured by the escape of blood and pus into the meatus. They are removed by gentle mopping with pledgets of cotton-wool. With the aid of the Siegle's speculum any fluid remaining in the middle ear is aspirated and the incision carefully inspected to be certain it is large enough to provide adequate drainage. The meatus is again mopped out and the ear covered by a large pad of cotton-wool or tomentation.

#### AFTER CARE

The most important point in treatment is the maintenance of adequate drainage. The condition to be dealt with is an acute abscess and any interference with the free escape of pus will retard resolution. Such interference may be encountered at any of three stages during resolution.

1 Immediately after incision of the tympanic membrane the opening may become filled with blood-clot thus preventing all drainage and defeating the one object of the operation. To prevent occlusion in this manner the ear should be inspected two to four hours after myringotomy has been performed. If any blood clot is present this is gently extracted with aural forceps or removed by carefully syringing with warm boric lotion after the application of a few drops of hydrogen peroxide (10 vols). When cleansed by this means the meatus is dried out with pledgets of cotton wool.

2 When the discharge of pus from the middle ear is profuse and cleansing either by syringing as described above or by frequent mopping is inadequate the accumulation in the depths of the meatus causes irritation and sets up oedema with further obstruction to drainage. In cases where the discharge is large in amount constant cleansing is required.

3 As resolution of the inflammatory process nears its end the discharge frequently tends to become thick and viscid. Neglect at this stage again leads to some obstruction to the escape of pus and consequent retardation of healing. The application of peroxide drops and syringing with boric lotion is the method of choice for cleansing.

Other causes of inadequate drainage are a perforation that is too small or is badly situated and the formation of granulations on the edges of the perforation. The former is overcome by enlarging the perforation employing the technique described for myringotomy and the latter by cauterizing the granulations. To do this clearly the external auditory meatus introduce eight to ten drops of 10 per cent cocaine and keep in contact with the drum for ten minutes. Dry then gently touch the surface of the granulations with solid silver nitrate fused on the end of a fine probe. While proper drainage is of prime importance the prevention of an otitis externa has also to be borne in mind. A good prophylactic measure is to grease the meatus thoroughly with ung. hydrarg. ovi. flav. 1 per cent at least twice daily.

Numerous kinds of drops, lotions and powder have been advocated in the treatment of acute suppurative otitis media. For the most part their effect is confined to the external auditory meatus and provided they are non-irritant their use is harmless. If the principles of surgery described above are adhered to their use is unnecessary.

(To be continued)

## HEALTH OF SCOTLAND

### REPORT FOR 1937

The report for 1937 of the Department of Health for Scotland states that the improved standards of health generally have been maintained. The death rate per 1000 showed no significant change or even a slight increase in 1937 being largely accounted for by the influenza epidemic of the spring which was the most serious visitation of the kind since 1929. A distinctive feature was the low record maternal mortality rate of 4.8 per 1000 births which was slightly less than that for 1936 though still in excess of recent rates for England and many other countries. Changes are taking place in the relative seriousness of disease—for example morbidity statistics indicated that some 40 per cent of the increase among insured persons was attributable to chronic disease. School health statistics and inquiries showed that there was little malnutrition in the country although shortages of important elements were noted in the diet of the very poorest and deficiency of milk in the diet of a large section of the population.

#### Infectious Diseases

During 1937 some 94,000 persons were recorded as suffering from infectious disease a decrease of 1-10 per cent compared with the previous year. The main factor in the decrease was a fall in the number of cases of measles while against this whooping-cough was responsible for some 7,000 more cases and scarlet fever and influenza pneumonia for 2,000 more in each instance. Tuberculosis as a cause of death maintained during 1936 and 1937 the low record death rate of 7.4 per 100,000 established in 1935. The report points out that during recent years a good deal of research has been undertaken in Scotland to determine the extent to which human and bovine tubercle bacilli respectively are responsible for cases of death in human beings. In 1937 pulmonary tuberculosis was investigated the bovine type of bacillus was found to be responsible for the disease in 37 per cent of the 211 meningeal cases the percentage of bovine origin was 46.4 in children under 5 and 20.0 in cases of 15 years and over. In 208 cases of bone and joint tuberculosis the percentages were 46.0 and 29.7. There has been a marked incidence of diphtheria in Scotland during the past few years and in 1937 there were 10,960 cases with 426 deaths. It is pointed out that antitoxins of immunized cattle and diphtheria have made little progress and are not effective.

in the areas of only some half dozen local authorities, so that a wide extension will be necessary if the general incidence of the disease is to be influenced in future. A central register of available supplies of malarial blood for the treatment of general paralysis has been continued by the Department, but during the year only six sources of malarial blood were notified and eleven applications for an available supply received.

### Maternity and Child Health

The outstanding feature of the year was the passing of the Maternity Services (Scotland) Act, 1937, of which the general object was to secure that the standard of domiciliary maternity services in Scotland should be comparable with that of institutional services. Local authorities under the Act must arrange that there will be available to any woman who is to be confined in her own home, and who makes application, the joint services of a medical practitioner and of a certified midwife throughout pregnancy, labour, and the lying-in period, with the advice or help of an expert obstetrician if the practitioner should think this necessary. It is assumed that all confinements attended under these arrangements and expected to be normal will be conducted by the midwife alone, while the medical practitioner will attend only those cases in which either he anticipates some difficulty or he is summoned by the midwife. The present position is that the schemes of individual local authorities are being submitted to local representatives of the medical profession, and it is expected that the new service will shortly be in operation. Maternal deaths numbered 423, seventy-one less than in 1936, and the mortality rate for the year was 4.8 per 1,000 births as compared with 5.6 for 1936. This was the lowest maternal mortality rate in Scotland since the beginning of the present century. Infant mortality during 1937 was 7,050 as compared with 7,315 in 1936, the rate being 80 per 1,000 live births as compared with 82 in 1936. The chief causes of infantile deaths were congenital malformation and bronchitis with pneumonia. Among children between 1 and 5 years, whose estimated number was 318,000, the total deaths were 2,195 and the mortality rate 6.9 per 1,000, as compared with 7.6 in 1936. Among children of school age at 5 to 14 years deaths numbered 1,454 compared with 1,501 in 1936, and gave the lowest rate for this group yet recorded. The arrangements made by local authorities under the Notification of Births Act, 1915, for attending to the health of expectant and nursing mothers and of children under 5 years are based on home visitation by health visitors. In the large burghs health visitors are mainly whole-time officers of the local authorities, while in country areas local authorities usually arrange for the services of district nurses as part-time health visitors. At the end of the year there were 502 whole-time and 644 part-time visitors in Scotland with 254 welfare centres provided under the schemes. There are in Scotland approximately 767 beds allocated to maternity patients in local authority institutions and 624 in voluntary hospitals, a total of 1,391, in addition certain voluntary institutions take maternity patients as occasion requires. The report shows that cases of damage to the eyes as the result of ophthalmia neonatorum are still prevalent. The number of cases of ophthalmia neonatorum notified during 1937 was 1,688 as compared with 1,379 in 1936, and in the past ten years there have been fifty-eight cases in which there was appreciable loss of vision including seven of total blindness. Under present arrangements a routine medical examination of school children is made on three occasions during school life. The incidence of defects varies little from year to year. A remarkable fall has taken place in the incidence of rickets during the past twenty-seven years from 9 per cent in 1910 to 1.5 per cent in 1937 and this is attributed as regards Glasgow largely to the provision of new open-air schools and open-air classrooms.

### Highlands and Islands

During the year the county council of Caithness appointed a consultant surgical specialist in that county and the trustees of the Belford Hospital at Fort William appointed a whole-time surgical officer and superintendent of the hospital. A scheme is now in progress for the erection of a new general hospital for Shetland, with the aid of a substantial grant from the fund. The Department has also instituted a scheme of grants for surgeons in the Highlands and Islands who undertake an approved refresher course at one of the large hospitals. The Highlands and Islands (Medical Service) Scheme now operates in regard to 151 medical practices. Grants were paid to county councils in respect of twenty removals by aero plane ambulance of urgent cases.

### National Health Insurance

There were 30,754 cases of "chronic" invalidity in the year to June 30, 1937, accounting for 11,225,210 days of incapacity, or about 40 per cent of the total days of incapacity in the year. This is equivalent to one insured person in every sixty being unfit for work throughout the entire twelve months. In order of importance, nervous diseases (mostly insanity), rheumatic conditions, circulatory conditions, tuberculosis, and bronchitis together account for two-thirds of the chronic cases. So important did this matter appear that the Department instituted an intensive investigation into it, which was being actively prosecuted during the closing months of 1937. Dental benefit continued to be the most important of the additional treatment benefits, and accounted for £271,060 during the year under review. The number of insurance practitioners in Scotland has varied little in recent years and on January 1, 1937, was 2,025. The total sum paid to them in capitation fees (excluding mileage) was £867,150. The mileage allowances to doctors in county areas of the Lowlands amounted to £42,500, and £10,000 was paid from insurance funds towards expenditure on the Highlands and Islands Medical Service. The number of prescriptions issued by doctors and dispensed by chemists for insured persons was 3,073,038, the number per person being 1.73, as compared with 1.72 in the previous year.

The report may be obtained from H.M. Stationery Office, 120, George Street, Edinburgh, price 3s 6d net.

## RHEUMATIC DISEASE A TRANS-ATLANTIC BROADCAST

An international broadcast on rheumatic heart disease, arranged by the American Heart Association in co-operation with the Empire Rheumatism Council, took place on Monday, May 2.

### England to America

Lord HORDLER, chairman of the Council, speaking from London, greeted America as the sturdy warrior in all campaigns against disease. The greatest monument to the triumphs of medical research, he said, was the Panama Canal which American engineers were able to build only by first abolishing tropical disease in the area. He hoped that America would do as good work against rheumatic disease which if cancer was excepted was 'public enemy No. 1'. In the United Kingdom rheumatic disease was the greatest of all the killers though it concealed its murders under the mask of heart disease. The line of combat must be first by research to discover the causative factors, and then by diligent effort in the field of preventive medicine to build up effective barriers. There was much evidence that the type of rheumatism which affected the heart was closely associated with bacterial infection, and it would surely not be long before

this association was clarified. But sociological factors, environment and possibly heredity must also be considered. Lord Horder said that he had recently had the opportunity of studying the figures of the incidence of acute rheumatic disease among 30,000 youths in certain training institutions. All of them had been examined and passed as first class lives. The greater proportion were drawn from the poorer classes and among these the incidence of acute rheumatism in a year was nearly 5 per thousand and of other forms of rheumatism over 7. But in the smaller proportion who were drawn from well-to-do classes the cases were so infrequent as to be almost negligible. Here was a clear indication of a sociological factor. Acute rheumatism was an infectious disease but some circumstances of early environment made the child's body a more favourable soil in which infection could flourish. Lord Horder then described the work of the Empire Rheumatism Council which he said welcomed the prospect of a close alliance with the United States in its investigations. He closed with a splendid vision of a world from which all preventable illness had been banished in which sickness was only the penalty of wickedness or of folly. The vision might be made a reality if men were wise enough to see the futility of fratricidal strife.

### Speeches from the U.S.A.

Three speeches were made from America. Dr WILLIAM J. KERR of San Francisco expressed the co-operative spirit of the American Heart Association. According to statistics of the U.S. Public Health Service half the deaths due to heart disease occurred before the individuals had lived their normal span. Rheumatic heart disease alone caused 40,000 deaths every year and the average age of the victims was 40. Many clinical and laboratory studies were being undertaken in America on the subject and the American Heart Association was in a position to suggest how funds might be usefully employed. Dr HOMER SWIFT of the Rockefeller Institute for Medical Research followed with a short discussion on the causes of rheumatic disease. Climatic factors he said seemed very important along the North Atlantic seaboard. In some southern climates the incidence was less and the attacks as a rule more mild. Rheumatic heart disease rarely occurred among inhabitants of the Tropics unless they had contracted it elsewhere. Unfortunately it was not often possible for the susceptible individual to remove himself permanently to a favourable climate but sanatoriums in good situations comparable with those existing for tuberculosis were being provided either by voluntary endowment or by the public health authorities. Dr T. DUCKETT JONES of Boston Mass. added some remarks on the treatment of rheumatic heart disease dealing especially with the need for prolonged rest in bed which allowed the body to conserve its energy for the fight against the disease process. But it was also important concurrently with rest to protect the patient from anxieties and emotional difficulties and to educate both the patient and his family. Recently attention had been drawn to the possibility of the transportation of patients to a tropical or semi-tropical environment, but a word of caution must be spoken for such a method had not proved so far entirely satisfactory and was by no means a panacea. The establishment of small isolated non-tourist centres was desirable but the difficulty was to arrange medical and nursing care.

The day on which the broadcast was made was National Child Health Day in the United States. The broadcast was made at midnight (London time) but was received in New York and other cities early enough to allow of meetings being held the same evening to discuss the subject.

Dr Robert Richard has devoted his inaugural thesis (*These de Paris* 1937 No 790) to a description of the floods which have devastated Paris from the sixth century down to the present day. The floods were followed by epidemics of enteric fever, bacillary dysentery and malaria as well as by famine until the middle of the nineteenth century, since when they have been prevented by hygienic measures.

## OPHTHALMOLOGICAL CONGRESS

The annual congress of the Ophthalmological Society of the United Kingdom was held in London at the house of the Royal Society of Medicine on Thursday, Friday and Saturday April 28, 29 and 30.

### Causes of Exophthalmos

Mr R. FOSTER MOORE opened an interesting discussion on the differential diagnosis of the causes of exophthalmos. His paper included an analysis of 114 consecutive cases of proptosis not due to Graves's disease. Mr J. H. DOUGART followed with a consideration of the differential diagnosis in children. Mr T. E. CAWTHORNE discussed the problem from the point of view of the ophthalmologist. Among many interesting cases he mentioned that of a man who developed extreme proptosis after he had his nose suddenly. The proptosis was due to surgical emphysema probably caused by the rupture of an ethmoidal air cell. Such cases were no unusual after severe trauma as in boxing. Dr W. RUSSELL mentioned a South American gentleman who could locate either globe forward from the orbit, the mechanism being doubtful. Mr D. V. GORDON described a similar forward dislocation in a Pekingese dog. In these animals the condition was not uncommon and not always reducible so that the eye might have to be removed. Mr F. W. LAW gave an account of a sudden proptosis in a well-known oarsman following an orbital haemorrhage. Dr E. E. POCHIN discussed a not uncommon illusion in Graves's disease where unilateral proptosis was sometimes diagnosed though the actual condition was in fact a unilateral retraction of the upper lid. Close examination revealed a marked superior palpebral crease on the affected side. The lower lid was also at a slightly higher level in such cases. Mr A. F. MCCALLAN discussed the inflammatory causes of proptosis.

### Arteriovenous Aneurysm of the Cavernous Sinus

Arteriovenous aneurysm of the cavernous sinus region was the subject of a paper by Mr A. D. GRIFFITH and Mr J. ELLISON. The condition was usually traumatic in origin and ligature of the common carotid for its relief might be followed by hemiplegia. In view of this Mr Griffith described the procedure of temporary ligation of the common carotid, the ligature could be released if cerebral signs became manifest. Dr GORDON HOWES, the president of the Society, emphasized the possibility of cerebral complications following the attempted cure of cavernous sinus arteriovenous aneurysm by ligation of the carotid and considered the method of temporary ligation worth a trial.

Dr SPENCE MEIGHAN and Mr MICHAELSON described the clinical and pathological features of a case of glaucoma of the retina. They suggested that perhaps something more was required than the usual enucleation of the eye in such cases, possibly exenteration of the orbit or in some cases radium therapy. Mr M. H. WHITING discussed the so-called "meningoceles" of the orbit pointing out that they were usually meningo-encephaloceles.

Mr L. H. SAVIN described a case of acute iritis associated with acute gout of the great toe. Both conditions subsided dramatically after treatment with colchicum and dieting. Several other patients were described in whom gout appeared to have been the cause of ophthalmic disease. Mr Savin reviewed the literature of ophthalmic gout pointing out that in the last century many cases which would now be diagnosed as gonococcal in origin were then termed cases of "gout." He could find a number of instances in which ophthalmic gout had been verified pathologically. Mr F. W. LAW referred to argemone seeds as those mysterious white or brown vessel-like lines in the fundi which always puzzled ophthalmic surgeons. In

one instance an angioid streak seemed to be a retinal fold on histological examination, though by reason of the method of fixation adopted exact correlation by measurement could not be carried out. Miss E. E. CASS, Miss M. B. DOBSON and Mr E. B. ALABASTER discussed abnormal retinal correspondence and kindred topics.

### Anatomy and Physiology

On Friday morning Mr E. WOLFF described certain aspects of the anatomy of the optic nerve-head. The disk was pink after embolism of the central artery because it received its blood supply from the circle of Zinn. Miss IDA MANN gave a most interesting survey of the history of contact lenses, ranging from the hydrodiascope of Young in 1801 to the modern Dallos lens, with its individual scleral fitting and its ground and optically accurate corneal segment. Dr DOUGLAS ROBERTSON brought forward data which disproved the theory that the aqueous humour was a dialysate, he considered that the aqueous humour was a secretion. Sir STEWART DUKE-ELDER agreed that the aqueous was not a dialysate, but doubted whether available evidence went so far as to prove that it was a secretion. Mr F. T. RIDLEY suggested that normally the aqueous might be a dialysate, but the mechanism of its production might be modified under certain pathological and physical conditions. Mr T. H. HODGSON did not find from his experiments that the aqueous could be considered a dialysate. Fallacies in previous work had been due partly to the fact that no allowance had been made for alterations in blood-osmotic pressures due to the method of anaesthesia adopted for experimental animals.

Mr HARRISON BUTLER, next year's president, described a case of recovery from a severe post-operative iridocyclitis with hypopyon after the administration of prontosil; the patient had previously had gonorrhoea. Mr F. A. JULER pointed out that severe iritis with hypopyon sometimes cleared spontaneously. Mr R. LANG described a case of gonococcal conjunctivitis in which prontosil had proved valueless.

### Treatment of Epiphora

On Friday afternoon Mr A. GAYER MORGAN read a paper on the treatment of epiphora. In occlusion of the nasal duct in infants he always tried conservative measures first. When probing was necessary he passed the probe through the upper punctum. Intranasal lupus was a cause of epiphora in older children likely to be overlooked. In adults 80 per cent of infected sacs were seen in females. He analysed twenty-five cases in adults in which he had performed the operation of Dupuy-Dutemps, the sac being drained into the nasal cavity through a hole in the bony partition with the two mucous membranes anastomosed. The results in nineteen cases were completely successful, in two partially so, four cases were failures.

Mr A. SORSBY and his colleagues reported on cases of phlyctenular disease seen at White Oak Hospital, Swanley. Considerable evidence was produced to show that tuberculosis played a part in the aetiology of most of the cases, but in a minority group of a slightly different clinical type no evidence of tuberculous disease could be obtained. In the evening Mr Sorsby demonstrated two patients with fundi stained by a harmless green dye. This was injected either intramuscularly or intravenously, and brought out details which might otherwise be obscure, such as small holes in a detached retina.

### Methods of Anaesthesia

On Friday evening there was an interesting discussion on methods of anaesthesia applicable to ophthalmic operations. Mr T. K. LYLE reported on 930 cases in which evipan anaesthesia had been used at the Royal Westminster Ophthalmic Hospital. He said that even children now-

adays were "injection-conditioned," and so suitable for evipan anaesthesia. Jactitation was unusual under evipan anaesthesia, particularly if omnopon and scopolamine were given before operation, the airway had to be maintained. Mr BASIL GRAVES and Dr E. S. ROWBOTHAM discussed the advantages of paraldehyde analgesia. Considerable discussion followed on the technique of cataract extraction under such analgesia (see *Journal*, 1937, 2, 319). Mr Graves and Mr H. B. STALLARD described their experience with corneal stitches. Mr E. R. TRIVY thought that excessive attention to detail slowed down the normally quick course of a cataract extraction. He did not believe that any special advantage was gained by the unduly slow performance of the operation or by unnecessary mutilation of the eye by redundant procedures.

Dr T. R. HILL read a paper on the relation between neuromyelitis optica and certain cases of disseminated sclerosis.

On Saturday a new apparatus was demonstrated by Mr R. H. RUSHTON for measuring the axial length of the human eye *in vivo* taking advantage of the fact that the dark-adapted eye is sensitive to x rays, it was thought that this apparatus might be of assistance in investigating the problem of myopia. Dr E. C. DAX described how he had found a substance in the urine of eleven cases of retinitis pigmentosa which would disperse the melanin granules of frogs. This substance had never been found in the urine previously except in pituitary disorders. Miss D. R. CAMPBELL and her colleagues described a form of abiotrophy of the retina in rats, considered analogous to human retinitis pigmentosa. Dr T. J. NICHOLL disputed the validity of the Wagenmann experiments on which the vascular theory of retinitis pigmentosa was based. Mr M. L. HEPBURN supported this theory. Mr HAINES showed a new instrument for investigating dark adaptation. Mr P. MCG. MOFFATT described the use of acetylcholine in the treatment of tobacco amblyopia.

### THE ANNUAL BANQUET

On the evening of April 26 the annual banquet of the Ophthalmological Society was held at the Langham Hotel, with the president, Dr Gordon Holmes, in the chair. In proposing the toast of "The Society" Dr Holmes said that it was founded in 1880, and of the sixty-three original members three survived—Sir George Berry, Sir Thomas Barlow, and Sir Lindo Ferguson of Dunedin. The twofold aim of the founders—the scientific study of the eye and its disorders, and the bringing together of all interested in ophthalmology—had been pursued throughout. Ophthalmology to-day held the position it deserved in the medical profession, its eagerness to keep contact with medicine as a whole brought reciprocal benefit. The health of the guests was proposed by Dr Percival J. Hay of Sheffield, who welcomed in particular Sir Cuthbert Wallace, P.R.C.S., Surgeon Vice-Admiral P. T. Nicholls, Medical Director General, R.N., Air Commodore A. V. J. Richardson, Director of Medical Services, R.A.F., the Master of the Clothworkers Company, whose interest in the welfare of the blind was well known to the members, and the Editors of the *Lancet* and the *British Medical Journal*. Sir John Parsons, who replied as President of the Royal Society of Medicine, found difficulty in thinking of himself as a guest at this gathering of fellow ophthalmologists. Major General W. P. MacArthur, Director General A.M.S., also responded to the toast, and acknowledged the Society's hospitality in a few graceful words. The health of the President was proposed by Mr Leslie Paton, one of his earliest friends in England, who called up memories of long-past days at Queen Square, and claimed a share in linking neurology and ophthalmology in the person of G. H. He said that Gordon Holmes, as a neurologist, president of the Ophthalmological Society, was a worthy successor to Hughlings Jackson.

## TRAVELLING FELLOWSHIPS IN MEDICINE

The Medical Research Council invites applications for its Rockefeller Medical Fellowships for the academic year 1935-36. These are provided from a fund with which the Council has been entrusted by the Rockefeller Foundation of New York. They are intended for British graduates who have had some training in research work in clinical medicine or surgery or in some other branch of medical science and who are likely to profit by a period of work at a centre in the United States or elsewhere abroad before taking up positions for higher teaching or research in the United Kingdom. The stipend will ordinarily be at the rate of £360 per annum for a single Fellow and of £480 per annum for a married Fellow. Travelling expenses and some other allowances will be paid in addition.

The Council also invites applications for four Dorothy Temple Cross Research Fellowships in Tuberculosis which are awarded from a special endowment of which the Council is trustee. The object of these Fellowships as defined in the trust deed is to give special opportunities for study or research to suitably qualified British subjects of either sex intending to devote themselves to the advancement by teaching or research of curative or preventive treatment of tuberculosis in all or any of its forms. The stipend will ordinarily be at the rate of £360 per annum for a single Fellow and of £480 per annum for a married Fellow with an allowance for travelling and incidental expenses.

Completed applications for Fellowships of either type must be lodged with the Council not later than June 1, 1936. Further particulars and forms of application are obtainable from the Secretary, Medical Research Council, 58 Old Queen Street, Westminster, S.W. 1.

## Reports of Societies

## THE HANDICAPPED CHILD

At a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on April 27, Sir ARTHUR MACNALLY, presiding, an address was given by Dr W. ALLEN DALEY of the London County Council on *School Life and After for the Handicapped Child*. It was illustrated by a film showing the special services of education in London and by specimens of the handiwork of children in special schools.

Dr Daley said that by a handicapped child he meant one who by reason of mental or physical disability was at a permanent disadvantage both at school and in after life. Certain American writers termed these children the "underprivileged." They comprised mental defectives, cripples, deaf and partially deaf blind and partially sighted and epileptics. Parliament had required local education authorities to provide special education for the blind and deaf since 1893 and for the mentally and physically defective since 1899. The present law relating to the education of handicapped children was contained mainly in Part V of the Education Act 1921 and briefly was to the effect that education authorities had certain duties as to (1) the ascertainment of the defective and (2) the provision of special education.

## Extent of the Problem

He next considered the size of the problem taking for this purpose the London figures as ascertainment was probably as complete there as anywhere in the country. The numbers of children in London attending special schools in 1936 (excluding those attending open air schools for delicate children and those in hospital schools) were as follows:

## Children at Special Schools

Defect	Number	Rate per 1,000 School R.
Verall defective	3,752	6.9
Physically defective	3,451	6.3
Epileptic	117	0.2
Blind	111	0.2
Partially blind	63	1.2
Deaf	6	0.01
Partially deaf	1-3	0.01
	3,66	1.7

In the case of the mentally defective the big figure was reached just before the war. The physically defective showed a continuous tendency to rise but this was due to the increasing number of cardiac cripples admitted. Those crippled in limb were less numerous than formerly. The figures for the blind and partially sighted showed a decrease during the period 1918 to 1925 after they had steadily until two or three years ago since when they had declined. There had been little change in the figure for the deaf and partially deaf. The decline in the certifications of both the mentally and the physically defective since 1930 was an indication of the rapid fall in the number of London's school children and the falling birth rate.

## Mental Defectives

Children might be required to attend schools if they were mentally defective from the age of 7 and might be retained until 16 if when due to leave the local education authority was of opinion that further institutional care, guardianship or supervision was required; the names of the children had to be forwarded to the local mental deficiency authority. The feeble-minded with whom he was specially concerned in this connexion were capable of deriving benefit by education in special schools and classes and so possibly taking a place in the community later on although that place might be a lowly one. They could be taught usually to do a varied range of very simple often of low grade and occasionally learnt a simple expert process. The mentally defective child usually came to notice in school by his failure to adapt himself to his surroundings and to learn. It was the duty of his head teachers when satisfied of this failure to bring such children to the notice of the school doctor who in his turn must satisfy himself that there existed no marked physical defect such as deafness or defective vision which of itself might account for the backwardness. It was then his duty to refer the child for statutory examination by the approved medical officer. The diagnosis of mental defect was not the mere arbitrary application of a scale of intelligence tests such as the Binet-Simon scale or one of its modifications. It was based upon a complete survey of the child's physical and mental reactions supported by evidence of his medical and educational history and was very properly the province of the medical man alone. In practice it was shown that educable mental defectives had intelligence quotients between 20 at the lower limit and 70 at the upper. The number of children in the schools for the mentally defective in London in 1907 was 3,840 being 7.9 per thousand of the children in the elementary schools. In 1917 the rate was 10.6 in 1927 9.2 from which figure it had fallen continuously until in 1936 it was 7.4. Dr Daley thought that it must be concluded that there had been some slight decline in the proportion of feeble-minded children in the London school population during the last ten years.

The functions of the school for mental defectives were two: to teach the defective by means of a modified curriculum.

culum directing his footsteps to some occupation he could usefully follow, and to stabilize him. The stabilization resulting from years of discipline and training under the care of specially experienced teachers was by far the more important function. When a child in such a school attained the age of 15 the question arose whether he needed the protection of the Mental Deficiency Acts. The head teacher reported on a special form setting out the child's attainments; the school medical officer signed the certificate of feeble-mindedness except in the rare cases where at this late stage, it was decided that the diagnosis was not justifiable and it was for the education committee to decide after careful scrutiny of the reports whether the case should be passed over to the mental deficiency committee for supervision, guardianship, or institutional care. Of the 563 children notified to the Mental Deficiency Committee in London in 1936, 486 were placed under supervision and of this number two-thirds had found work and one-third were out of work. The occupation followed by defectives under statutory supervision was chiefly factory work, but the list included lorry drivers, plumbers, soldiers, tailors, and even canvassers and travellers.

### Physically Defective Children

The number of children in the schools for the physically defective in London in 1936 was 3,451, being 6.8 per thousand of the elementary school population. The rate ten years ago was 6.0, and twenty years ago 5.4. An analysis of the causes of crippling showed that children crippled in their limbs had been replaced by those crippled by heart disease. The proportion of cardiac cripples now in the special schools approached 50 per cent of the total. There had been a considerable decline in the proportion of children crippled by tuberculous disease of bones or joints.

*Children Admitted to Schools for the Physically Defective*

	1921	1926	1931	1936
Tuberculous bones and joints	254	255	215	100
Rheumatism, chorea, and acquired heart disease	282	327	611	325

Inquiry had been made in 1,900 unselected cases on the register of the After-Care Association in December, 1937, and showed that 85 per cent of these children had had some work since leaving school. The proportion certified as unfit for industrial employment was 3.3 per cent.

### Children Deaf or Blind or with Mixed Defects

The London County Council provided six day and two residential schools for the deaf. Recently twenty-three group hearing aids had been installed in the special schools for children with defective hearing. These were powerful amplifiers which give the ordinary radio signals, but which by means of a control converted the radio amplifier into a microphone to convey the sound of the teacher's voice to the children through their earphones. Children who could not develop speech naturally, and hitherto had been taught by lip reading, now had the advantage of sound stimulation through the normal channel and could thus learn by sound patterns in conjunction with visual patterns. The deaf had little difficulty in obtaining and retaining employment.

There had been a very gratifying reduction in the number of blind children of school age in London. The number on the school roll in 1914 was 415 or 0.62 per thousand; in 1936 it was 85 or 0.17 per thousand. All the day schools for the blind had now been closed as it was impossible to find enough blind scholars to fill them and the work was limited to two residential schools. The

classes for the partially sighted were a more difficult and controversial problem. London was the home of such classes, which were first established in 1908 on the advice of Mr. Bishop Harman, then consulting ophthalmic surgeon to the Council. There were now ten such schools in London. The number of scholars reached its maximum (981, or 1.57 per thousand) in 1929. In 1936 the number was 632 (1.25 per thousand), and was still declining. It had lately been suggested that a stricter selection of myopes should be exercised, and criteria for admission were recommended which would exclude certain children. These were based on an attempt to differentiate between physiological and pathological myopia, selecting only the latter for the special classes. It was admitted, however, that there was no certain method of differentiating between the two, and as damage might result while ordinary education of a pathological myope was continued, the position was by no means satisfactory. It was clear that further research into the problems of myopia was urgently necessary.

The outstanding feature of the London special school service was the Rayners School (residential) at Penn for children with mixed defects. All were deaf, and some were, in addition, mentally defective, some deaf and blind, or partially sighted, and some deaf and crippled. It was a finely situated country house in delightful grounds, and the patience of the teachers was beyond praise. In fact, in such a school the teacher's art reached its highest point. Of 264 pupils who passed through this school between 1921 and 1936, 161 were now self-supporting and thirty-nine others were in employment, though not of a self-supporting nature. With regard to epileptics, it was only when the fits were really troublesome that arrangements were made for the child to be sent to a colony. London maintained 117 epileptic children in the various colonies, this being 0.23 per 1,000 on the school roll, and the ratio had not altered appreciably for some years.

Dr. Daley concluded with some remarks on the hospital schools of London, of which there were eleven; the number of children in these schools at the end of last year was 2,738. Of this number those described as suffering from rheumatism amounted to 773, and from tuberculosis 652. These hospital schools played a very important part in both the public health and educational services of the county. The bodies of the children were restored to health, which often took many months and sometimes years, and meanwhile their minds were not neglected. Their lessons often had a therapeutic value and ensured also that when their in-patient treatment was completed they could take their part in the educational system, either in ordinary or in special schools.

Dr. BERNARD SCHLESINGER followed with a film illustrating the routine in hospital schools for cardiac cases, in particular at the Children's Heart Hospital at West Wickham. Dr. J. G. JOHNSTONE, orthopaedist to the London County Council, mentioned that the incidence of non-pulmonary tuberculosis in London had fallen by 69 per cent during the last fifteen years. He mentioned the great importance of continued after care, after care of these patients should not cease on leaving school.

Dr. C. E. THORNTON, divisional medical officer in charge of the Council's rheumatism scheme, said that in 1926 the school doctors found, out of about half a million children examined, that 0.2 per cent were suffering from some form of acquired valvular disease. In 1936 the percentage was 0.8 per cent. Dr. A. G. WELLS gave some account of schools for the deaf, and dealt with the special handicaps of the partially deaf. He pleaded for the passing into legislation on behalf of the deaf some measure corresponding to the Blind Persons Act. Two headmistresses of schools for the physically defective gave an encouraging account of their experience, and Dr. CLARA TROTTER, as medical officer of health for London, brought paid a high tribute to the work of the London County Council.

## THE NEW DIVORCE LAW

At a meeting of the Medico Legal Society on April 28 with the President SIR TRAVERS HUGHREYS in the chair Mr WILLIAM LATEY (barrister at law) read a paper on the medico legal aspects of the Matrimonial Causes Act 1937

## Questions of Unsound Mind

Mr Latey said that Mr Herbert's Act introduced several elements about which the court would depend for guidance and elucidation on the medical profession. The court would have to determine whether a respondent in a divorce suit brought under sect 2 had been continuously under care and treatment for at least five years, was of unsound mind, and was incurably so. The Act contained no definition of the words of unsound mind and a court appeared to be prevented by the word and from basing a finding of unsound mind merely on the fact of five years continuous care and treatment. It could not be taken for granted in all cases that a person who had been under detention or supervision for five years was of unsound mind. A petition could not be served on a respondent alleged to be of unsound mind unless the medical attendant was satisfied that the communication would not be detrimental to the respondent's mental condition. This threw a heavy responsibility on the medical officer. A famous divorce judge Sir Gorell Barnes in *O'drovd v O'drovd* (1896) had applied the test. Is the condition of unsoundness of mind such as makes married life impossible or intolerable? That test however had only been used in considering a question of restitution of conjugal rights and in the far more serious issue of dissolution of marriage the court might be disposed to give a stricter interpretation.

To a layman the terms of unsound mind presented a bewildering variety but he could see that medical science had made enormous advances in prognosis and cure. It might be surmised that the courts would require cogent evidence from the medical attendant of the degree of the respondent's insanity. The evidence would need to be still stronger if the patient had not been certified but had sought treatment voluntarily. An important question when the courts would have to consider was whether the evidence should show that the patient would never be fully mentally sound again or whether he would never be certifiable again should he be discharged at any time from care and treatment. In one case the court might feel bound to dissolve a marriage where the doctors thought that the patient might recover sufficiently to take his place in society and lead a harmless life but that his mind would not achieve complete normality. A difference of opinion between doctors has already appeared in certain instances, and some medical attendants and superintendents had at first declined to give an opinion for the purposes of the Act. A letter in the *Times* of March 12 had questioned whether giving information would constitute a breach of professional confidence. Refusal would stultify the law especially for poor persons who could not afford an outside specialist. Moreover the outside specialist would need access to the records before forming his opinion. The difficulty could be overcome if there were a panel of medical inspectors of the court functioning in the same way as medical inspectors in cases of nullity and impotence.

## Grounds for Annulment

The Act provided for a decree of nullity on grounds of insanity at the time of the ceremony. The Marriage of Lunatics Act, 1811 made it impossible for a lunatic to contract a legal marriage even during a lucid interval. In a certain number of cases during the last thirty years decrees of nullity had been granted on the ground of mental incapacity to understand the nature of the contract. Some people had only heard of this old law

as a result of making inquiries about relief under the new Act. Lawyers would be interested to know whether epilepsy in any form could be regarded as one of these diseases of the mind which incapacitated a sufferer from truly appreciating the implications of marriage. Further the Act provided that a marriage could be annulled on the ground of wilful refusal and the new Matrimonial Causes Rules did not oblige the petitioner in such a case to go through the formality of medical inspection but merely permitted an application by either party, to examination by the medical inspector of the court. If the putative wife petitioned it was possible that the court would require proof of her virginity though probably the evidence of a private practitioner and examination would suffice. Where the petitioner was the putative husband it was an open question whether or not the court would require an examination of the respondent in an undetected case. It was well known to be extremely difficult to determine virginity. Probably in this kind of case gynaecologists would often be called upon to give expert evidence. The Act further provided that a spouse might petition for nullity within a year of the ceremony, the husband or wife had been at the time of the ceremony suffering from communicable venereal disease. Any spouse who contracted venereal disease except from the one spouse was already held *prima facie* to be guilty of adultery. A divorce had been granted on these grounds because a husband was suffering from cutaneous venereal itch (*Stead v Stead*, 71 Sol J 391). Whether or not his disorder should properly be regarded as a venereal disease within the meaning of the new Act would probably depend on expert medical opinion. It would also be to decide to decide whether inherited venereal disease was communicable.

## General Discussion

The PRESIDENT said that the question of incurability would not be left to medical witnesses to decide any more than were a great many other matters on which they gave evidence. *Prima facie* the court would be guided by the opinions of experts. The judge would as in every other kind of case come to his conclusions of fact upon the evidence before him. Mr. F. J. MCCANN spoke of the fallibility of the appearance of the human as a guide to virginity.

DR J. L. MOIR declared that the Act had been a failure. Before its passing the law of lunacy, detention and detention should have been entirely reformed and put on a safe sure and scientific basis. Before a man was branded as of unsound mind he should be examined by a panel of experts and they should also assess the curability of his condition. There would then be a record of five years be a record which the court could use if a petition were presented. The British Medical Association had been advised that if a doctor gave an opinion upon the curability of a patient he would not be protected by the Mental Treatment Act from an action for damages. Venereal disease could be contracted innocently and the Act would apparently make it a ground for nullity even if it were not genital.

SIR ROBERT ARMSTRONG JONES declared that it was almost impossible to detain a curable mental patient more than five years. Apart from the formalities of certification before a year had expired a medical statement of his condition must be made to the Board of Control. Statements must be made at the end of the second, fourth and sixth years and every five years afterwards to the effect that he is still of unsound mind and a proper person to be kept under care and treatment. Moreover the Board of Control was to deliver an opinion in each calendar year every five years and in every licensed house in the London area six times and out of twice the justices having to make four visits. It was highly improbable that a patient would recover after five years. Cases were reported from the

to time, but they made up less than 5 per cent of all mental patients

DR R D GILLESPIE said that the Bill had filled medical men with a considerable amount of anxiety. Mental hospitals were already unpopular enough with the public and he was surprised that medical superintendents had not stressed the possible effects of the Bill when it was passing through Parliament. Perhaps it was an aftermath of this realization that made medical superintendents reluctant to give information about a patient's condition. They were deterred by a natural loyalty to their patients, apart from any desire to protect themselves. If a medical man were carrying out the law, he might state the facts without being accused of breach of confidence, just as he did when he was called in to grant a certificate without the patient's knowledge. Patients occasionally recovered after very long periods of insanity, but an extreme conservative attitude to this possibility might stultify the intentions of the Act. "Curable" and "recoverable" were not identical terms.

The PRESIDENT in closing the discussion, said that the court would have to decide whether the respondent, who must have been of unsound mind for a substantial period, had been shown by the evidence to be so unlikely ever to be cured as to be for practical purposes incurable. All that any doctor could be expected to do was to say that, taking all the known facts into consideration, he had formed the opinion that the patient could not recover. Incurability would be judged with regard to the necessities of married life. Perfection in prophesying the future was not to be expected, and the court would have to do its best.

### THYROTOXICOSIS

At a meeting of the Manchester Medical Society on April 6 Mr F H BENTLEY read a paper on an inquiry into thyrotoxicosis.

Mr Bentley described the late results of partial thyroidectomy for thyrotoxicosis, and discussed the relationship between thyrotoxicosis and gastric acidity. General clinical examinations, estimations of the basal metabolic rate, blood counts and fractional gastric analyses (with histamine) were carried out on eighty-four patients—twelve males and seventy-two females—more than six years after partial thyroidectomy had been performed for thyrotoxicosis. The average lapse of time since the operation was eight years. The clinical results showed 40 per cent of the patients completely well with no symptoms of any kind, 23 per cent completely well except for some palpitation on exertion, 30 per cent improved and working but still with some complaint such as nervousness, tiredness, dyspnoea or irritability and the results in 7 per cent were unsatisfactory. One third of the cases had at the present time a basal metabolic rate of plus 20 per cent or more, and a quarter of the cases had palpable thyroid tissue in the neck while a few of these belonged to the 'completely well' group. The majority belonged to the less satisfactory groups. It was suggested that there was some evidence in this series that the sympathetic hyperactivity continued in many cases after thyroidectomy, and that the sympathetic hyperactive state preceded the thyrotoxic one being an agent in stimulating the thyroid into the increased activity of thyrotoxicosis. The gastric acidity had been studied in ninety thyrotoxic cases pre-operatively—seven males and eighty-three females—as well as in the later post-operative series. In the pre-operative series there was anaecidity in 22 per cent after correction of the figure for the normal incidence of anaecidity and 81 per cent of the cases had a maximal acid secretion of less than 40 units following the injection of histamine. The corresponding figures in the late post-operative series were 7 per cent and 69 per cent respectively. Thus the secretion of acid which was depressed during thyrotoxicosis showed

improvement after thyroidectomy, but acid secretion did not return to a normal level. While there was no relationship between depression of acidity and the duration of symptoms, a tendency for the depression to be more marked in the severe thyrotoxic cases was noted. Apparently two factors were involved in the depression of gastric acidity in thyrotoxicosis, one was removed by thyroidectomy, so permitting acid secretion partially to rise, and one continued to act, maintaining acid secretion at a subnormal level. The former factor was probably thyrotoxic sympathetic stimulation resulting from the thyroid toxæmia, and the latter sympathetic stimulation—a part of the sympathetic hyperactivity in which thyrotoxicosis originated and which continued after thyroidectomy.

### ENGLAND AND WALES

#### International Red Cross Conference

The preliminary programme has now been issued from 14, Grosvenor Crescent, SW 1, for the sixteenth International Red Cross Conference to be held in London next month (from Friday, June 17, to Saturday, June 25) under the auspices of the British Red Cross Society. After business meetings on June 17 and 18 the opening session presided over by the Duke of Gloucester, will be held in St James's Palace on June 20, followed by a plenary session and an evening reception by the Government at Lancaster House. On June 21, 22, and 23 there will be meetings of commissions at British Medical Association House, Tavistock Square, with a reception at the Guildhall on the evening of June 21. June 24 will be given up to a plenary session, the closing session of conference, and a meeting of the Board of Delegates. On the last day the Board of Governors of the League of Red Cross Societies will meet at 14, Grosvenor Crescent, and a thanksgiving service at St Paul's Cathedral will follow at 3.30 p.m. Delegates from over sixty nations and National Red Cross Societies will attend the conference, which had originally been arranged to meet in Madrid. Prominent on the agenda is the consideration of the revision of the Geneva Convention. It is hoped that new principles dealing with war in the air will be proposed, and that the Geneva and Hague Conventions may be merged so that land, sea and air warfare will be dealt with in a single code of laws. A plan for the creation of neutralized hospital zones in war areas, sponsored by the International Congress of Military Medicine, will also be discussed.

#### Extensions at Staffordshire General Infirmary

The extensions to the Staffordshire General Infirmary are to be opened by Lord Horder on Saturday, May 7. They consist of an 'L'-shaped wing of three floors. The ground floor is occupied by a new x-ray, electrotherapeutic and massage department, and other improvements to be housed here are an electrocardiograph and a larger clinical laboratory. On the second floor is a male surgical ward of twenty beds and a children's ward of sixteen beds, together with the usual sanitary annexes, kitchen, and duty rooms. The upper floor is an up-to-date private nursing home, a complete unit in itself, containing four teen single bedded rooms for paying patients, with bath rooms, kitchen, visitors waiting-room, duty room and sterilizing room. Each room is fitted with a built-in wardrobe, wash-basin, connexion with the public telephone and a luminous call system worked from the beds. Special attention has been given to making the building soundproof, and the colour schemes throughout are light and pleasing. Each ward kitchen has a refrigerator. The walls and ceilings are sound- and heat insulated, and the

heating is by a low pressure hot water system capable of sustaining a minimum temperature of 65° F when the outside temperature is at freezing point. The Infirmary was founded in 1766 and is one of the oldest voluntary hospitals in the provinces. William Withering one of the most famous figures in medicine and renowned for the discovery of the use of digitalis in certain forms of heart failure spent some ten years of his career as physician on the staff of the hospital. Modern medicine has still no better drug to offer for the treatment of heart failure than this extract of the common foxglove and Stafford should always be remembered as the place where Withering made his early pharmacological studies.

#### Presentation to Dr Spurgin

The jubilee dinner of the Metropolitan Police Surgeons Association was held on April 28 at the Holborn Restaurant with Dr Percy B Spurgin the retiring president in the chair. A large number of members and their friends were present among the guests being the Commissioner Sir Philip Game Dr P B Skeels Sir William Willcox Dr Isaac Jones and other members of the headquarters medical staff and Dr G C Anderson. The evening was most successful the main feature being the presentation of a silver salver to Dr Spurgin by his colleagues as a mark of their appreciation of the work he has done for the Metropolitan Police Surgeons Association for many years, both on the council and as treasurer.

## IRELAND

### The Public Health

Recent annual reports of the Department of Local Government and Public Health for the Irish Free State have noted a gradual decline in the incidence of infectious diseases. The report for 1936-7 however states that the number of cases of the principal infectious diseases notified during 1936 increased from 7,478 the figure for 1935 to 9,924. This increase was due almost entirely to the epidemic of scarlet fever which was widespread throughout the country during the latter part of 1936 and the greater part of 1937. The incidence of diphtheria however continues to decrease the total number of cases reported during the year was 2,569 as against 3,091 in 1935. The fall is attributed to the vigorous immunization campaign which has now been carried generally into rural districts. On the subject of maternal mortality the report states that notwithstanding the attention this problem has received no substantial reduction in the death rate from pregnancy or child bearing has taken place in recent years. The rate in 1936 was 4.7 per 1,000 births the figures for the two preceding years were 4.67 and 4.65 respectively. It is considered that improvement could be gradually effected by extending maternity and child welfare schemes to all districts developing existing schemes to provide ante natal care for expectant mothers and institutional accommodation for difficult cases or for women whose home conditions are unsuitable encouraging closer co-operation between the mothers health visitors midwives and medical practitioners, and making arrangements for adequate feeding of expectant mothers whose family circumstances are not sufficient to enable them to obtain the extra foods necessary during pregnancy. Infant deaths reached a total of 4,309 representing a mortality of 74.15 per 1,000 births the highest rate recorded since 1926. This high figure was due largely to an increase in the rate in Dublin county borough and Dr Russell the medical superintendent officer of health stated in his annual report that deaths from diarrhoea and enteritis were mainly responsible and that cows milk carelessly handled during transit from the cow to the infant is frequently the vehicle for these infections.

### Puerperal Sepsis in Dublin

In the *Journal* of April 20 there appeared at page 95 an annotation on the planning of maternity hospital. The same subject with special reference to the needs of Dublin was discussed at a recent meeting of the Section of Obstetrics of the Royal Academy of Medicine in Ireland. Dr A H Davidson Master of the Rotunda Hospital thought that a special isolation hospital was necessary for cases of puerperal sepsis it should be in the charge of an obstetrician who would have the assistance of a bacteriologist and a house surgeon. Dr C J McSweeney suggested that such an isolation block should be in the charge of a physician with the assistance of a consultant obstetrician and might well be part of the new Dublin fever hospital. He said the Queen Charlotte Septic Block a unit of thirty beds cost £7,503 exclusive of the bacteriological department which was estimated to cost over £4,000. Situated in a fever hospital such a unit would not cost half as much. Dr J F Cunningham Master of the National Maternity Hospital believed that the problem would be better solved by the establishment of a special department connected with one of the general hospitals. Dr R M Corbett Master of the Coombe Hospital thought the arrangement of the Frith Auxiliary Hospital in Shemeld three miles from the Jessop Hospital with which it was affiliated ideal for the treatment of puerperal infection. Dr Falkiner supported the suggestion that the cases should be nursed in an isolation block connected with the fever hospital. He agreed that it would be necessary to accommodate some 200 cases a year and thought it would be advisable to make puerperal pyrexia no more in Ireland. The discussion ended inconclusively but there was general agreement on the need for special accommodation for cases of puerperal sepsis though some difference of opinion as to how this could best be provided.

### Radiological Conference in Belfast

The programme has now been issued for the fourth annual general meeting of the British Association of Radiologists to be held in Belfast on Friday May 13 and Saturday May 14 at the Whitley Medical Institute, College Square North. The proceedings will open with the installation of the president Dr R M Beath who will give an address followed by a paper on Chronic Flaccid Paralysis as seen from a Radiological Standpoint by Professor P Flemming Moller of Copenhagen. The first part of Friday afternoon will be devoted to Radio-diagnosis the discussions being opened by Dr T Garrett Hardman of Dublin Dr J F Brailsford of Birmingham and Dr Peter Kerley of London. After tea at the Royal Victoria Hospital there will be an inspection of the Hospital Centre and the annual dinner of the Association at Thompson's Restaurant. On Saturday morning a symposium on Radiotherapeutics will be led by Dr S Cochrane Shanks of London Dr J Ralston Paterson and Margaret Todd of Manchester and Dr R McWhirter of Edinburgh. In the afternoon there will be golf at New Eddlestone and an excursion to Larn and Ballinacastle. Full particulars can be had from the Secretary British Association of Radiologists 32 Welbeck Street London W1.

An announcement regarding the award of Farnham Research Foundation fellowships for cancer research was made in the columns on November 20 1937 (p 1057). The secretary of the Foundation Dr William A Farnham Medical and Chirurgical Faculty Building 1211 Cathedral Street Belfast more than now apply a statement of how they are selected for one year at a recent meeting of the Board of Directors. One of the selectors Mrs Margaret E Farnham for years with Professor E L Kennaway at the Royal Cancer Hospital London. Applications for next year should be in the hands of Dr Fisher on January 1 1939 the appointments being made in March 1939.

## Correspondence

### The Incision for Appendicectomy

SIR—The annotation on the incision for appendicectomy in your issue of April 16 (p 860) entirely ignores the oblique muscle cutting incision in the right iliac fossa, which was brought before the profession by Emeritus Professor Rutherford Morison many years ago (*Edin med J* March, April, May, 1897, *Lancet* February 23, 1901). This incision is almost universally employed by the surgeons of the Newcastle School, and, having been used in thousands of cases of all variety, it can now be said to have stood the test of time and to have come out with flying colours. Since coming to London I have frequently had the opportunity of demonstrating this incision to numbers of postgraduates, and I know that many of my younger friends have not only adopted it but are enthusiastic as to its possibilities and advantages.

I would, however, like to take this opportunity of emphasizing the necessity for care in closure. This must always be done carefully in layers with interrupted sutures, and the surgeon must always use sufficiently strong catgut. I always employ No 3 for the deeper muscles and No 1 for the aponeurosis and in both cases I use catgut of the chromicized variety. It would be wrong to say that incisional hernia never occurs but I think it is quite fair to claim that it is not more frequent or more troublesome than the hernia which may occur after any of the other incisions which are commonly employed in dealing with acute appendicitis—I am, etc.,

London W 12 April 28

G GREY TURNER

### Origin of Cancer

SIR—Although the papers by Drs W E Gye and W Cramer which have recently appeared in the *Journal* are of the greatest possible interest as indicating the trend of present-day investigations, I find the letter of Dr J V Fiddian (April 30 p 973) of exceptional importance. In it he suggests a line of approach to the problem which so far has been neglected. The current idea seems to be that as the essential nature of cancer is a purposeless increase of proliferative cellular activity, such activity is due to some factor or factors which enter the cell from without. It does not seem to have occurred to the pathologists that an alternative explanation may be that the important factor is really an intrinsic one which has been all along inherent in the cell and only fulminates when a certain controlling mechanism has been put out of action.

In order to follow this latter line of thought we may take as a simple example the grandfather clock. Here the impulses to function are two in number and are inherent in two weights which are wound up weekly, the force is due to the gravitational pull of the earth and its potential is greatest when the weight is at the top. The descent of the weight in each case is controlled by a certain mechanism—in the one instance an escapement regulates the rate of revolution of the hands, in the other a striking mechanism fixes the striking times. By altering the length of the pendulum we may cause the clock to go too fast or too slow but it still ticks along at an even rate. If however we were to knock out the escapement altogether the clock would race so fast that it would soon destroy itself. Altering of the escape-

ment" may possibly explain the occurrence of benign tumours such as adenomata, lipomata, etc., and "complete elimination of the escapement" would explain the occurrence of malignant growths.

Thoughtful American palaeontologists when they observed long ago the sequence of changes occurring along certain definite lines during the slow upward evolution of great morphic groups of plants and animals found themselves impelled to postulate an evolutionary driving force, which as it acted in an apparently purposeful manner they called orthogenesis. More recently other thinkers have revived the same idea under the name of emergent evolution. As to the actual nature of these factors, although neither of these schools seems to be more clear than Topsy was when she speculated as to how she "grewed," they both agree that without some form of driving force phylogenetic evolution would have been impossible.

Some years ago it occurred to me that there is a remarkable parallelism between the development of the individual and the development of the group. Both begin in the simple and proceed to the complex, and each, after it has reached a certain culminating point, passes steadily to extinction. The life of the group is simply a long series of individual lives, working from below upwards, and there seems to be in the case of each group, as there is in the case of each individual, a certain definite fixed point beyond which further progress is impossible. It would seem as if the upward evolution of the group is dependent on the presence in the germ cells of a certain definite quantum of developmental energy or driving force. This is carried on through the successive generations at a slowly diminishing rate until it is exhausted, when the group dies. At each conjugation of ovum with spermatozoon a certain definite amount of developmental energy is liberated from a potential state and placed at the disposal of the zygote, just enough to carry on the ontogeny of the individual then starting its career. The ontogenetic process is controlled and governed by the genes which keep the driving force within bounds until the end of the individual's life when, the supply of force being exhausted, the individual dies.

In my opinion Dr Fiddian has definitely indicated a line of approach to the solution of the cancer problem when he states that the act of conjugation between spermatozoon and ovum "endows the resulting zygote with sufficient reproductive impetus to carry on cell division at a gradually reduced speed until the final exhaustion and death of the organism. Whether Dr Cramer's "sudden change" is due to conjugation between two pre-cancerous cells or is due to a process which first damages and finally knocks out the controlling (escapement) mechanism, as I am suggesting remains to be seen. Perhaps we are both very wide of the mark—I am, etc.,

Ramsey, Isle of Man May 1

E G FENTON

SIR—To say that our want of success in handling the cancer problem is due to ignorance of fundamentals is to stress the obvious. As conditions of viability are so narrowly defined a minute change in them can throw the whole system out of gear. Colloidal lead which although it has been used systematically, defeats its own purpose as it acts more powerfully constitutionally than locally. There are a number of chemicals which act locally and so exert only negligible general effects which might be employed to disorganize new growths. We are constantly making leather when treating patients suffering from severe burns as the action of tannic acid can be greatly accelerated by

an electric current surely it would be worth while to determine its effect on a superficial tumour. It by means of this or any other coagulant a practical method of treatment be found our knowledge of fundamentals will remain just about the same. If we are to employ the method used with such striking success by the great physicists, and seek to determine the unknown by establishing the quantitative relationships of two or more known properties we cannot afford to neglect any means which will broaden the foundation on which we base our reasoning. While we cannot use the flying particles which have enabled the recent great advances in physics to be made we can turnish moving pictures of systems in actual operation and so compare pathological and normal tissues. Moving pictures of cell life enlarged and appropriately slowed would afford marvellous revelations of intracellular action and allow ample time in which to study them. With a system at work under his eyes anyone accustomed to correlating quantities could not fail to increase our knowledge. Recurring problems in biology which involve multiple variables probably simply indicate that we have not found the common denominator which will reduce them to a single term. Apparently we shall have to seek to interpret vital action in terms of electric potential, to extend Volta's pile to include organic electrolytes, and to correlate potentials, valencies and the pH. It is a chastening reflection that while the physicist can tell us so much of bodies of the order of one millionth of one-millionth of a centimetre we know so little of the cell—a relatively huge organism—I am, etc.

Montreal April 12

RICHARD KERRY

### Fracture of Neck of Femur

SIR—The greatest barrier to progress is complacency. Mr Eric I Lloyd (*Journal* April 16 p 871) is commendably determined that we shall not be complacent about fractures of the femoral neck. But his pessimism calls for some of my optimism. He says Watson-Jones at Belfast this year, frankly admitted that his figure of 91 per cent had proved optimistic. I was reporting a subcapital fracture nailed and apparently cured in which removal of the nail after twelve months had been followed by re-fracture within a few days. Union was less sound than had appeared. What I frankly admitted was that I did not know how many more of my 91 per cent of apparently successful results were of this variety. I still do not know and I am certainly not proposing to remove any more nails to find out. I shall be content to wait for post mortem examinations to satisfy my scientific curiosity.

But there is more pessimism to neutralize. Nails break completely across in 8 per cent of cases. I am astonished. I have yet to meet one single personal case of a fracture of the femoral neck in which the nail has broken. Nails slow down union considerably. Where is the evidence? We cannot compare cervical fractures with each other because some have a normal blood supply to the head some an impaired blood supply and some no blood supply at all. It is the vitality of the two fragments which determines the rate of union. Because a few nailed subcapital fractures are not united even after twelve months we must not blame the nail. These are the cases which do not unite at all without a nail. Trochanteric fractures can be more closely compared because there is no vascular disturbance. In these cases the evidence suggests that union is accelerated not delayed by nailing. And it is because recovery is accelerated and facilitated that it is worth nailing many basal fractures.

On the other hand I entirely agree that it is not worth nailing impacted abduction fractures. These unite so rapidly without any treatment at all that operative procedures must surely be superfluous.

Mr Eric Lloyd's most profound observation is that the bad results of nailing are the results of bad nailing. One wishes that this aporism might be stamped on the head of every three flanged nail—I am, etc.

Liverpool April 24

R WATSON JONES

SIR—The statement that the abduction fracture of the neck of the femur should not be nailed must be examined with care.

We know that in reducing the ordinary abduction fracture perfect reduction cannot be obtained and a degree of slight coxa valga gives a good functional result. But these abduction fractures have frequently got an associated posterior displacement which is only shown in the lateral photograph and though the impaction may appear to be a disimpaction may occur or union may be delayed. I have recently seen three abduction fractures which had been treated conservatively—for example fixed in bed on a Thomas splint or plaster of Paris—and in which severe arthritis developed within five years. In the first patient the displacement shown in the antero-posterior radiogram was slight but when performing the arthrodesis one could see that displacement had occurred in the antero-posterior plane. It is for this reason that I object to the statement that the abduction fracture should not be nailed. However I admit that coxa valga *per se* can even be an advantage.

In my experience the disadvantages of the Smith Petersen nail enumerated by Mr Lloyd are rather common nor serious. I should have said that nail erosions were so unimportant that nobody mentioned it. I find it difficult to believe that nails break completely across in 8 per cent of cases. It has occurred twice in my sixty-six cases, one of which was nailed six months after fracture. I assume that a patient has bony union when six months after nailing clinical and radiological evidence appear to show that union has taken place. Presumably why Mr Lloyd considers that the Smith Petersen nail is superior to union is because it is acting as a foreign body but this is more than counterbalanced by the complications which it affords. I agree that one should wait three years before finally assessing ones end results but not three years before determining whether or not union has taken place.

The advantage of nailing the per trochanteric fracture is not the advantage of getting union as I admit that this occurs in any event but of getting union in good position without adduction and in this fracture adduction occurs only too frequently. One also obviates the drawback of having to restore mobility in the knee and there is the added benefit of never losing the mobility of the patient—I am, etc.

Norwich April 26

H A BRITAIN

### Injection Risks

SIR—In your annotation on injection risks (*Journal* April 30 p 955) the statement is made that the usual way is to autoclave every syringe and needle after each use, or an ideal unattainable in practice. This prompts me to mention a method which I have used for some years in preparing Record syringes (Maw's heat resisting) for blood cultures and hypodermic injections.

Three squares of Kraft brown paper about 8 inches by 8 inches are prepared. In one the plunger is wrapped with collar in position, the barrel is enclosed in a paper

and the two small parcels thus formed are wrapped together in the third piece which is secured by string. The divided syringe is then autoclaved at  $105^{\circ}\text{C}$  for fifteen minutes. After sterilization the paper is dried thoroughly, and it has been found that sterility is maintained for months in bag or cupboard if the paper is unopened. Needles are autoclaved point downwards in small test tubes (4 inches by  $\frac{1}{2}$  inch), a small plug of cotton-wool protecting the point. The tubes are stoppered with cotton-wool and a Kraft paper cap is tied in position to prevent drenching of the wool. From such a tube the needle can be dropped on to the syringe without handling. By this method a supply of sterile dry syringes and needles is available for instant use. The method works with all sizes up to 20 ccm. It is extremely inexpensive because the paper and string can be used repeatedly. Its efficiency has been shown by a long series of uncontaminated blood cultures often collected under unsatisfactory conditions in hotels and private houses.

A practical point concerns the method of wrapping the barrel and plunger. The component is laid diagonally on the paper, two opposite corners of which are brought together and the parcel then rolled up. In this way when the outer cover is removed the paper of each smaller parcel presents two corners which when grasped and gently pulled apart open the package, exposing the sterile component lying untouched on a sheet of sterile paper. In private practice a domestic pressure cooker would probably be quite effective as an autoclave.

The method is an adaptation of that used in bacteriological laboratories for the preservation of the sterility of pipettes—I am, etc.,

Bath April 30

H J GIBSON

### Dosage of Tuberculin

SIR—May I support Dr W Camac Wilkinson's refutation of the statement that the subcutaneous tuberculin test is not now used for diagnosis (*Journal* April 23, p 921). At the thirteen tuberculosis dispensaries of Down County Council and in numerous cases in Co. Down where the test doses are given by private practitioners under my direction test doses in doubtful cases of tuberculosis are still being given "with eminent success and no semblance of danger." Our method is as follows.

Having made sure that the patient's temperature does not exceed normal at any time of the day we give a first test dose of old human tuberculin (T) of 0.0002 ccm. After an interval of at least three days if no reaction has followed we give double the dose and so on up to six doses so that the sixth dose is 0.0064 ccm. If no reaction has occurred after the last dose we can assure the patient that he is not suffering from tuberculosis. If a definite reaction occurs at any stage the test doses are stopped and much smaller treatment doses begun. At the same time we can assure the patient that since the disease is so slight that it has had to be detected in this way a course of tuberculin treatment for six or nine months will make it all right.

It is unfortunate that statements by prominent physicians such as that quoted by Dr Wilkinson from *The Principles and Practice of Medicine* by Sir William Osler and Dr Thomas McCrae should have led to neglect of tuberculin. There is no doubt that harm can be done by wrong use but that is no good reason for not acquiring and teaching its proper use. I have still some reprints of a paper giving further particulars of our method and will gladly send a copy to anyone who asks for it—I am, etc.,

JOHN R GILLESPIE

Chief Tuberculosis Medical Officer,  
Co. Down

Belfast April 25

SIR,—I should like to endorse the remarks of Dr Camac Wilkinson on the dosage of tuberculin. It is indeed remarkable that such dangerous doses should have been quoted in a standard textbook of the standing of Osler and McCrae in three successive editions without comment. The fact that tuberculin administered subcutaneously has been largely abandoned as a diagnostic agent is no excuse for repeating dangerous and misleading information. From 1926 to 1928 I worked with Dr Camac Wilkinson and helped to administer tuberculin according to his methods, both diagnostically and therapeutically, in many hundred cases. I can say definitely that I never saw a single case harmed thereby. I have found myself unable to accept Dr Wilkinson's general thesis that a positive tuberculin reaction is in itself an indication for treatment, and therefore have found tuberculin of only limited value for diagnostic purposes. I am convinced, however, that in suitable cases it is a valuable therapeutic agent if administered according to the methods taught by Dr Wilkinson, and when so given is not dangerous—I am, etc.,

London, W 1, April 26

T W PRESTON, MD

SIR,—Having had twelve years' experience in the use of tuberculin, diagnostic and therapeutic, under Dr Camac Wilkinson at his Tuberculin Clinic I can confirm the truth of his assertion (*Journal*, April 23, p 921) that the administration by subcutaneous injection of 0.025 ccm or of 0.015 ccm original tuberculin, as suggested in *The Principles and Practice of Medicine* (Osler and McCrae) might be expected to produce disastrous results. What Dr Camac Wilkinson states that one-fiftieth of 0.015 ccm is a sufficient first diagnostic dose he is not in any way straining the truth. May it not be the case that tuberculin has been unpopular in the past through the recommendation in this, one of the leading textbooks in medicine, of such an excessive diagnostic dose? In my opinion it would be well worth while revising the dosage of tuberculin in the next edition of *The Principles and Practice of Medicine*—I am, etc.,

J GORDON HUME, MRCS, LRCP

London, W 1, May 2

### Insulin for Schizophrenia

SIR,—The leading article in your issue of April 23 (p 900) entitled "Insulin for Schizophrenia" calls for some comment.

Your leader writer mentions "spontaneous remission" in this disease, inferring presumably that this is entirely independent of treatment. The primary lesion in schizophrenia is definitely nuclear exhaustion and degeneration due to prolonged stress or shock of varying nature affecting neurones which are temporarily or constitutionally subnormal from a physical point of view. The obvious treatment, therefore, is the repair of the nuclear lesions before the decay has proceeded too far, and there is no doubt that with proper rest and care, suitable diet and treatment a high recovery rate may be expected if these cases are dealt with at an early stage, the great difficulty, as with other diseases but even more so with this affliction, is to get the cases under suitable treatment early enough.

There has been of late a marked and professional most regrettable tendency towards propagandism in relation to the treatment of mental disorder from the importation of psycho analysis to this country to the latest exotic—the production of coma by the depletion of glucose from the body fluids. The presence of

crystalloid in a definite concentration is just as much a necessity to the maintenance of normal physiological processes as any of the other normal constituents of the tissues, such as globulin leucithin etc. It is probable indeed that a normal glucose concentration in view of its influence on the stability of the colloidal constitution of the body fluids is of even more importance than is the case with other constituents. It just happens however that injection of insulin through the resulting sudden depletion of glucose affords a ready method of bringing about a spectacular and dramatic shock to the entire system of an extremely dangerous nature and closely verging on dissolution. To subject an early recoverable case of schizophrenia to such an irrational and gross experiment before trying treatment based on relieving the pathological condition present is an unwarrantable and entirely unscientific proceeding—I am etc

Stafford April 24

B H SHAW M.D.

### "Gonococcus Antitoxin" for Gonorrhoea

SIR—In the *Journal* of February 13 1937 (p 321) there was published a paper by Dr T Anwyl Davies on a new specific antitoxin treatment for gonorrhoea. In this paper Dr Anwyl Davies made a fairly substantial claim for this new treatment and since he is the director of the St Thomas's Hospital venereal disease clinic probably the largest and best known venereal disease clinic in the country, his results no doubt created a considerable impression among venereologists. Although I made certain pointed criticisms of the clinical technique employed in the work (February 20 1937 p 415) Dr Anwyl Davies's results were not again challenged until the publication of the comprehensive work on the same subject by Dr E T Burke and his three collaborators (March 19 1938 p 605).

Dr Anwyl Davies noted the great discrepancy in the clinical results (March 26 p 701) and wrote "Contradictory results in an attempt to evaluate new forms of treatment are of course not unknown. It is to be hoped that the cause of the failures described will be discovered as obviously the situation cannot be left as it is at present. Assuredly it cannot be left in its present condition but it is Dr Anwyl Davies who seems at the moment to be chiefly responsible for so leaving it. Otherwise apart from dealing with my general criticism of his clinical technique why does he not reply to the queries of Dr Burke and others (April 2 p 755) when they wrote

It would be interesting to know the reasons which prompted Dr Davies to use a dosage so much smaller than that which he recommended originally. Dr N Seaton-Taylor (April 16 p 872) wrote "Finally, it would be interesting to know whether or not Dr Anwyl Davies used protosol or some allied substance in some or all of his cases by way of adjuvant. To know the answers to these queries is not only interesting but vital if the object of the clinical researches undertaken is to be elucidated. If Dr Anwyl Davies is sincere in his affirmation regarding this anomalous state of affairs then he must reply to these most relevant questions put to him—I am etc

Enfield Middlesex April 25

W LESTER

SIR—I have read with interest the article by E T Burke J Gabe A H Harkness and A J King (*Journal* March 19 p 605). I started using gonococcus antitoxin as soon as it was available in India. I treated eight cases with this serum and eight more with vaccines (four with gonoderm and four with Glaxo Laboratory's

intracutaneous vaccine). All the sixteen cases received intracutaneous prostatic massage dilatations etc. No special follow-up was made of cases for serum treatment. All the eight cases under serum treatment showed a more rapid alleviation of symptoms and earlier recovery. This result combined with my previous observation of nine other cases treated with vaccines has convinced me of the value of the gonococcus antitoxin. I must mention however that one of these eight serum-treated cases did develop a severe articular rash after the tenth injection. This happened in spite of the fact that adrenalin had been given him with every serum injection. This particular patient had an infection of long standing. He had been treated by various doctors with all available remedies. Relapses occurred fairly regularly and frequently. The longest period of freedom from symptoms was three months. After serum treatment he has remained free for over six months and has never felt ill since. I am etc

Lahore India April 24

C V RAICHANDANI

### Nasal Sinusitis in Childhood

SIR—Mr James Crooks in his article on nasal sinusitis in children (*Journal* April 10 p 955) says "Sinusitis has a bad reputation and one is told that it is never cured for life. On broad lines and except in the case of suppurative sinusitis I agree and I do not think that so-called catarrhal sinusitis is often cured. In my opinion this is because most cases of sinusitis begin as allergic allergic reaction which is localized in the nasal mucosa and the mucosa of the sinuses. This is why operations on the sinuses and repeated removal of the allergic polyps or polyps are unsuccessful. Treatment of the mechanical condition as by removal of the polyp does not cure the patient. I have treated numbers of cases of sinusitis for their allergic condition—and with merely local treatment—with excellent and permanent results. I make a very strong plea for the conservative treatment of sinusitis and would suggest that those trying it will not be disappointed—I am etc

Liverpool April 10

J BERNES

### Pasteurization of Milk

SIR—After some months complete absence from this country my attention has been drawn to the policies of the British Medical Association as revealed in the recent prominent advertisement on Safe Milk and on the special value of pasteurization as the essential remedy for the existing national milk problem. I have read carefully all the correspondence for and against that policy which has appeared in the columns of the *Journal* in the past few months. As one who has always taken an active and sustained interest in nutrition both in its scientific and practical aspects and who has also during the past few years as the owner of probably the largest dairy herd in this country utilized the opportunity of acquiring a first hand knowledge of the milk problem in its various aspects including the merits of pasteurization as carried out in accredited hands I venture with the greatest respect to the B.M.A. to offer a word of criticism to the profession. Medical men are rightly responsible for the profession. Nevertheless it behoves them to take precautions lest they lend themselves quite unwittingly to the support of legislative measures advocated in all good faith which are costly and adequate investigation and making the long run calculated to be much more useful to a political party than to the public and the medical profession.

It is beyond the scope of my present purpose to reply to the various points in favour of a general pasteurization policy raised in your correspondents' letters. I wish rather to correct the erroneous impression which was, justifiably in my opinion, drawn by many Scottish members of the Association from the official pronouncement of the parent body. In response to a recent inquiry directed to Dr Craig the Scottish Secretary of the Association as to whether the advertisement adequately and correctly represented the views and policy of the B.M.A. I am informed that the official view of the Association is 'perfectly correctly' expressed in the following statement:

The important point to keep in mind is that the B.M.A. and other bodies which advocate pasteurization are not asking that it should be made obligatory. They are urging that local authorities should be given the power to exclude from their community milk which is not either pasteurized or derived from tuberculin tested (or in Scotland, certified) herds.

This is, in my view, a sound pronouncement, and one which would probably make a fairly universal appeal to Scottish readers of the *Journal* and if adequately emphasized, it would correct the erroneous impression which was widely drawn from the original statement.

The present position of the milk problem recalls a former experience. Some years ago the question of compulsory pasteurization received a good deal of consideration in Parliamentary circles in relation to impending legislation on milk. A very short time before the subject came up in Parliament I was rung up one evening from London by a prominent Scotchman with a long and intimate knowledge of the subject and also with considerable knowledge of Parliamentary procedure. He informed me that he had that day authoritatively learned that in the opinion of one or more prominent medical men in Government circles a scheme for the compulsory pasteurization of milk would be included in the legislative measures proposed, and that it was likely to go through. He further made the suggestion that a copy of an article on the subject which had appeared in an accredited journal of agriculture some time previously should be sent immediately to every member of Parliament. This was done. When the subject came up for discussion in Parliament a week or two later the acting spokesman of the Government made a statement to the effect that whatever the merits of pasteurization were that subject did not come up for discussion. So far as I know no fresh data of a scientific or other kind are now available to justify any change.

In conclusion keeping in view the point raised by Dr Kirkland in his interesting letter which appears in this week's issue I hope that none of your readers will imagine that the fact of my being a "milk producer" in any way unduly influences my opinion and recommendations.—I am, etc.

DRUM A.B. MAY 1

CHALMERS WATSON M.D.

SIR—It almost seems as if no amount of evidence is going to persuade some people of the necessity for a pasteurized milk supply. I think we might sum up the B.M.A. arguments in this way. We admit the right of any individual farmer or town dweller, to drink any kind of milk (or water) that he likes. But we do not admit the right of any person publicly to sell or to distribute, either for profit or as propaganda, either milk (or water) which he cannot guarantee free from known agents of impurity, either chemical or bacterial. Would these same producers and distributors of unpasteurized milk, and their sup-

porters, be willing to answer in a court of law a charge of having supplied milk "to the danger of the public" "without due care and attention," and "while under the influence of"—pathogenic bacteria?—I am, etc.,

WIMBLEDON, S.W. 19, April 29

G. I. WATSON

SIR—Dr James Kirkland's last letter (April 30, p. 979) is an unconscious admission of weakness in the case for pasteurization. In place of reasoning we have assertion. All experimental evidence is brushed aside. "The buck and doe test cuts no ice, this can be said of most tests." Yet presumably Dr Kirkland has some belief in milk tests made by himself or else he would close his laboratory. "The fall in the birth rate is not, as we know well, dependent on diet but on those preaching a gospel of birth control—whether rightly or wrongly does not enter into this discussion." I like the parenthesis "as we know well," because personally, having studied the birth rate problem for the past sixteen years, I did not know it was so simple. Nor does anyone else who has given the matter more than a moment's consideration. Causation of vital changes is never simple, and there are at least a dozen factors influencing the birth rate, although not germane to this discussion.

"A healthy nation, even supposing it should be slightly less fertile, is far and away a sounder proposition than a large nation whose stamina is undermined by a contaminated milk supply." That is the kind of statement that passes for logic in these illogical days, but the point is whether, once national decline begins, there is going to be any nation at all. And why should there be no alternative between contaminated milk and the pasteurized product of the combines? "Of course, an ideal milk is a raw milk, provided such can be produced that is clean, pure, and uncontaminated. To this day such a milk has never been procurable." I can assure Dr Kirkland that the people of Finland, the most democratic country in Europe, have such a milk supply. If possible in Finland, why impossible in Britain? Even in London I obtain raw clean Jersey milk from the Express Dairy Company for 8d per quart, summer price. No cow that is negative to day to the tuberculin test will be positive in three months' time unless infected in the interval, and infection can be prevented. Only 0.02 per cent of all cows in Finland are tuberculous. Over 40 per cent of cows in Britain are tuberculous. These are truths that ought to be advertised.—I am, etc.,

LONDON, W.8 April 30

HALLIDAY SUTHERLAND

### Multiplicity of Special Diplomas

SIR—Dr F. G. Nicholas's letter in your issue of April 23 (p. 922) requires, I think, a brief reply. First as to personal inconsistency, I am a firm believer in a one-portal entry into medicine, and do not think there should be more than one higher diploma, obtainable perhaps in twenty different ways. I do not, however, propose to tilt at windmills.

Your correspondent says that I am in error when I state that a radiological diploma in this country may be taken within a year of graduation. The University of London states in its Regulations: "The course is open to registered medical practitioners. Students are required to attend a course of study extending over not less than one academic year." The Regulations for the Conjoint Board diploma are the same. Cambridge University demands three months' experience as a resident house officer before allowing candidates to enter upon a diploma course, but it is still possible to take the diploma within a calendar year, if not within an academic year.

He further states: "The present diploma is of little value. The blame must be laid at the door of those who are now awarding themselves foundation Fellowships. As a member of one of the preliminary committees I speak from personal recollection when I say that it was found impossible to get the various college and university authorities to establish a diploma which was no in conformity with their other established diplomas as regards conditions of entry and time of study required. This was in fact one of the arguments which weighed with the Association of Radiologists in the establishment of a Fellowship. It wished to be able to put into force its own conception of what should be demanded of a diagnostic or therapeutic radiologist who wishes to have a knowledge of his subject comparable *ceteris paribus* with that of a surgeon possessing the FRCS."

Dr Nicholas is peculiarly unfortunate in asking what one would think of the Royal College of Surgeons if it held two examinations of different standards. That is exactly what it does—the MRCS which implies a general knowledge of surgery, and the FRCS which implies an expert knowledge. It would no doubt have been simpler if the Association of Radiologists had itself been able to grant both the lower and higher grade diploma but existing rights must of course be respected.

To quote your correspondent further he says: "All that need be done is either to abolish the diploma and retain the Fellowship or to raise the standard of the diploma to that of the Fellowship and then drop the Fellowship. Can he conceive the authorities at present responsible for issuing the diplomas suddenly raising their requirements from one to five years postgraduate work and issuing a diploma in radiodiagnosis or radiotherapeutics only?"—I am etc.

London W 1 April 25

F. HERNIMAN JOHNSON

### Why "A Cold"?

SIR—I have read Mr James Crooks's article on nasal sinusitis in childhood (April 30 p 933). In it the expression "a cold" without any definition whatever is repeatedly used. I suggest that the terms "a cold,"

"catching cold" and "a chill" should be dropped from medical literature as dangerous and misleading. In my opinion the perpetuation of these expressions is the chief enemy of public health to-day. A consultant working in hospitals, nursing homes and among the well to do where conditions are satisfactory and ventilation adequate is unable to appreciate the danger. This however is obvious to those working among the industrial classes and the poor. In connexion with treatment Mr Crooks mentions that "it should be started by keeping the child in a warm well-ventilated room. The lay mind naturally associates the expression 'a cold' with cold and in practice among a majority of the population last mentioned we find that sick-rooms are hermetically sealed. The windows are shut fast for fear that the patient will catch cold and the room may be warm—it is altogether too close and warm—but it is certainly not well ventilated which is much more important."

What is "a cold"? I take it that "a cold" is the same as the common cold to-day considered to be due to an ultramicroscopic virus. The confusion of thought arises from the fact that a person passing through a rigor has first a profound sensation of cold. But in these patients when the rigor occurs at the onset of more serious troubles—for example pneumonia—the infection is already caught and it will not be prevented by closing the window. Is "a cold" a nasal catarrh or is

the latter merely a symptom of it? What is a "cold"? Is this a cold associated merely with a vascular discharge? Suppose the catarrh goes on to the formation of mucopus? Must we call it merely "nasal catarrh" then? What about the term "febricula"? When must this be used?

I think it important that an unscientific expression like "a cold" should be dropped altogether. It would be much better to call the condition "influenza" (endemic influenza in contrast with epidemic influenza). In anything would be better than the use of the term "a cold" which causes the bacterial content of the atmosphere in rooms and trains to be many times greater than it otherwise would be if the fallacy of the causation of what is now known as the common cold were perpetuated in its present name—I am etc.

M. MELORAVE

### Referred Pains arising from Muscle

SIR—In your issue of May 12 (p. 94) Mr J. G. Campbell of Dundee writes in appreciation of Mr J. H. Kellgren's injection treatment of muscular pain. I have found these injections valuable also and would I have always used is 1 per cent. and 2 per cent. solution. I have used this method since 1922 and later although I do not claim it as an original idea. I have a vague recollection that I got the idea from *La Presse Médicale* to which I subscribed at that time. As Professor Lerone was a frequent contributor to that journal I am sure that I learned the method but the exact date is 1928—I am etc.

## Obituary

### THOMAS KAY DSO MB CM FRFSGS

It is with great regret that we have to record the death of Mr Thomas Kay which took place on April 20. Up to a fortnight before his death he had been in his usual health and had recently returned from a successful fishing holiday when he became suddenly ill with acute abdominal symptoms which developed into pelvic peritonitis, an abscess and paralytic obstruction to which in spite of operation he succumbed.

Thomas Kay graduated MB CM in Glasgow University in 1893 and after filling notice surgeon appointments with Sir William Macewen in the Western Infirmary studied for a time in Paris. He joined the staff of the Glasgow Royal Infirmary in 1902 filling the usual junior posts with distinction till in 1914 he was appointed visiting surgeon. With the outbreak of war he went to France in September 1914 and did not actually take up his duties as surgeon till demobilization in 1919. His term of service as a chef was relatively short as he retired from the Infirmary and on private practice in 1925 leaving Glasgow to live in Manchester where his home was a happy meeting place for his many friends and friends like himself enthusiastic golfers and fencers.

Kay had a distinguished military career in the South African War he served from 1899 to 1901 as a Surgeon and was awarded the Queen's Medal with five clasps and mentions in dispatches. He became a keen officer in the Territorial Army and when he was 60 he took out the Army

called up at once and served in France from 1914 till the end. In France he was first in command of a casualty clearing station, and later of a field ambulance, and was promoted A D M S 46th Division and 1st Division with the rank of colonel. He was awarded the D S O., was mentioned in dispatches three times and received the *Croix de Guerre*. The last military honour was that of Honorary Surgeon to the King—1927 to 1929. It is worth while quoting a note in the *Times* of April 25, contributed by the present A D M S 17th Division:

The death of Tom Kay will be deplored by all regular Territorial and temporary officers of the Royal Army Medical Corps either in the great war or after it. His high professional attainments are well known to all in the profession especially in Scotland but it was only those who served in intimate contact with him who knew how great was his unselfishness, his calm and courage in times of difficulty and danger and his whole hearted devotion to the interests of those who served under him. His casualty clearing hospital and later his field ambulance were extremely happy and efficient units and when he was promoted to be A D M S of a Division his departure was a loss recognized by all ranks of the 17th Division to which he had rendered such devoted service.

As a chief in the Royal Infirmary Kay will be remembered for his excellence as a good practical surgeon, an efficient teacher, and the head of a most happy unit. On his retirement he was appointed honorary consulting surgeon but he continued to give service to the Royal Infirmary as a manager from 1929 onwards. He had abundant leisure to devote to medical management and he gave to the hospital the best of his critical and constructive faculties. In addition to his Royal Infirmary work he was consulting surgeon to the Royal Hospital for Mental Diseases Glasgow, the Victoria Hospital, Helensburgh, chairman of directors of the Lock Hospital, and after he left Glasgow did a great deal of good surgical work gratuitously in a quiet way in Campbeltown and Kintyre. Kay possessed more than most men the gifts of happy good fellowship and steadfast helpful friendship. He was exceedingly modest about his surgical abilities and made no claim to scientific authorship but he was in all practical aspects a sound surgeon. Much sympathy is felt with his widow, daughter of one of Glasgow's well-known practising physicians, Dr John Fergus. The funeral service held in the University Memorial Chapel was attended by a large company representative of academic and professional interests.

J P

#### ARTHUR P LUFF, MD, FRCP

Consulting Physician St Mary's Hospital

We regret to announce that Dr Arthur Luff, CBE, consulting physician to St Mary's Hospital, died at his home in Limpsfield, Surrey on May 1. In 1932, at the time of the centenary he was elected a Vice-President of the British Medical Association in acknowledgment of his services as honorary director of collective research.

Arthur Pearson Luff was born in London on November 6 1856, the son of Richard Luff, and from the Western Grammar School entered the Royal College of Science, where he distinguished himself in chemistry and obtained the BSc Lond degree in 1883. He then studied medicine at St Mary's Hospital and graduated MB in 1887 with honours in medicine, forensic medicine, organic chemistry, physiology and materia medica, having already qualified as MRCS and LSA a few months earlier. He proceeded MD in 1889 and also took the DPH of the Royal Faculty of Physicians and Surgeons of Glasgow.

Dr Luff joined the teaching staff of St Mary's Hospital in 1887 as lecturer in forensic medicine, and held that post for twenty-one years, he was elected assistant physician in 1890, and on retirement from the active staff in 1913 was made a consulting physician. From 1892 to 1908 he was scientific analyst to the Home Office, and during those years his name became widely known in connexion with criminal investigations. He was elected a Fellow of the Royal College of Physicians of London in 1896, and in the following year gave the Goulstonian Lecture, taking as his subject the pathology and treatment of gout. An expanded version of this lecture appeared in book form and reached its third edition in 1907. He also wrote a *Textbook of Forensic Medicine and Toxicology* in two volumes, which was published in 1895, and was part author with Mr H C H Candy of a *Manual of Chemistry for Medical Students*, which reached a seventh edition. His *Harveian Lecture* on various forms of fibrositis and their treatment appeared in 1913. He had at various times been examiner for the University of London, the Royal Colleges of Physicians and Surgeons, and the Victoria University.

Dr Luff after retirement from the active staff at St Mary's, returned to work during the war, with the rank of Lieutenant-Colonel R A M C (T), as a *la suite* medical officer. For these services he was mentioned in dispatches and awarded the CBE in 1919. He was a member of the Departmental Commission on Preservatives and Colouring Matters in Food, which sat from 1923 to 1925. In recognition of his work in pharmacology and forensic chemistry he was awarded the Pereira medal by the Pharmaceutical Society and the gold medal of the Society of Apothecaries of London. He had joined the British Medical Association as far back as 1887, and when the idea of collective inquiries was revived some ten years ago he became a member of the Research Subcommittee and did valuable work as honorary director of collective investigations. The first of these was an inquiry into the treatment of varicose ulceration, it was followed by an inquiry into the after-history of gastro-enterostomy, and the third had as its subject the incidence of cancer of the breast and its history after treatment. His reports of these collective investigations appeared in the *British Medical Journal* in 1928, 1929, 1930, and 1932. While living in retirement at Limpsfield Dr Luff was made a Justice of the Peace, and for some years served as chairman of the Godstone Bench.

We regret to report the death on April 21 of Dr ALEXANDER THOMAS SCOTT MBE. Born in 1850 the son of the late Alexander Fairley Scott, he received his education at the Middlesex Hospital. He qualified MRCS, LSA in 1875, and held the posts of house surgeon and house-physician at that hospital. He was subsequently surgeon to the Holloway and North Islington Dispensary and to HM Prison, Holloway. Dr Scott devoted himself particularly to the work of the St John Ambulance Association, and was created an honorary associate of the Order of St John of Jerusalem and of the Order of Mercy. He was also distinguished for his work in connexion with the Special Constabulary, and received its medal with the 1914 bar. He joined the British Medical Association in 1891, and communicated various articles on surgical subjects to the *British Medical Journal* and other medical periodicals.

Dr ELLEN HEISE one of the first women to practise medicine in the United States died in California on April 13 at the age of 90. Her husband A William Heise had been a well known physician in the Civil War.

## Medical Notes in Parliament

Consideration of the Budget Resolutions of the Anglo-Italian Agreement and of the Eire (Confirmation of Agreements) Bill was the chief business before the House of Commons this week. In the House of Lords the Coal Bill and Housing (Agricultural Population) (Scotland) Bill were down for discussion.

In the House of Lords on May 2 the Inheritance (Family) Bill was brought from the Commons and read a first time. The Increase of Rent and Mortgage Interest (Restrictions) Bill which has passed the Commons was read a second time.

The Parliamentary Medical Committee met at the House of Commons on May 3. Sir Francis Fremantle presiding. Major S. H. S. Blackmore of the Air Raid Precautions Department addressed the meeting on air raid precautions. A discussion followed about the medical arrangements to be made at hospitals, first aid posts and clearing stations, and on the dangers from high explosives and from gases during an air raid. It is understood that a debate on the whole subject will take place shortly in the House of Commons.

The Nursing Homes Registration (Scotland) Bill was read a second time in the House of Commons on May 3.

The Local Authorities (Hours of Employment in connexion with Hospitals and Institutions) Bill introduced by Mr. Frederick Roberts has been dropped as also has been the Workmen's Compensation Bill introduced by Mr. John Jones.

The Prevention and Treatment of Blindness (Scotland) Bill introduced by Mr. Chapman which has passed through Standing Committee without amendment was set down for report stage in the House of Commons on May 6.

### The Budget

During a general discussion of the Budget Resolutions on April 28 Dr. EDITH SUMMERSKILL in a maiden speech said the County Council of Middlesex was unable to cope with its increased population. Hospitals were in a condition which made it necessary to take a patient out of bed at midnight in order to accommodate a more acute case. Builders were being asked such prices for new institutions that the county council was compelled to postpone new work.

Sir JOHN SIMON complimented Dr. Summerskill on her first effort but said he was a little surprised at what he said. The country was spending £50,000,000 more yearly on the social services than in 1931.

On the Report stage of the Budget Resolutions on May 3 an amendment to reduce the Customs duty on hydrocarbon oils from 9d to 7d a gallon was rejected. An amendment by Mr. H. G. WILLIAMS to reduce the Excise duty on spirits used for making power-methylated spirits was negatived. On the resolution raising the tea duty from 6d to 8d an amendment to reduce the duty to 4d was negatived.

### Cancer Death Rate

Sir KINGSLEY WOOD agreed with Mr. W. S. Liddall on April 28 that deaths from cancer in the city and county borough of Lincoln had risen from ninety-six in the year 1927 to 126 in the year 1936 and that cancer had now moved up to second place in the list of fatal diseases throughout the country. Mr. LIDDALL asserted that apart from occupational malignant disease this increase was due to the Minister's failure to recognize the urgent need for full provision for the adequate treatment of the many pre-cancerous general medical and surgical conditions. He asked what steps Sir Kingsley proposed to take. Sir Kingsley Wood did not take notice of the personal charge. He said that in any comparison of the numbers of deaths due weight must be given to the greater ages to which people now lived and the improved methods of diagnosis.

The work of the Radium Commission in recent years had resulted in the formation of a number of centres for the treatment of cancer, one of which was in Lincoln.

### Malaria in India

On May 2 Mr. DAVID ADAMS asked the Under-Secretary for India whether the financial loss suffered through malaria in India alone was between £23,000,000 and £20,000,000 per annum and what steps were proposed to check this loss. It was closely connected with inadequate access to chemical compounds or with unduly high prices due to inadequate supplies. Lord STANLEY said that the control of the production, distribution and sale of quinine and allied alkaloids was not a matter for the Provincial Governments. The Central Advisory Board of Health had the whole matter under consideration and passed resolutions on the subject in June.

**Hospitals and Air Raid Casualties**—Mr. W. THORNE asked on April 27 whether the Government intended to make a grant to hospitals treating cases of casualties from air raids. Mr. GEORGE LLOYD in reply said that in the case of hospitals designated as casualty clearing hospitals the local authorities would be able to make a grant under the Act.

**Incapacitating Sickness**—Mr. DAVID ADAMS asked on April 28 whether the Minister of Health was initiating a comprehensive investigation into the extent and causes of incapacitating sickness with a view to reducing the cost to the community of such items as the 31,000,000 weeks of working time now lost annually in this country from industrial sickness. Sir KINGSLEY WOOD replied that the matter was receiving no consideration.

## Medico-Legal

### SUCCESSFUL DEFENCE OF SCHIZOPHRENIA

In the case of Rex v. Phillips tried before Mr. Justice Atkin recently, the accused was a theological student of 21 who was found to have murdered and mutilated a boy of 16, a servant at his college, with no other motive than to act out a murder fantasy. He had attended early service on the morning after the crime, apparently without the slightest compunction. He was described as unusually reserved and unsociable and as having very strict and narrow religious views. Dr. Henry Yellowlees called for the case and said the accused was undoubtedly suffering from schizophrenia, a splitting of the personality. The disease was found to have been exactly the kind of emotional and ferocious that he had shown since the crime. He described the attitude of the young man as exactly comparable to that of a criminal who has been brought in from his solitary place to listen to the conversation of grown-ups in a drawing room. He was very interested and was slightly peevish. He had answered the doctor's questions without the slightest hesitation or evasion and said that until a week before the interview he had been thinking how the crime might be done again in a more satisfactory fashion. He had proposed to get a victim—it did not matter whom—and had talked about the necessity of looking for a suitable one. When he had obtained the victim he had played with the idea of taking off his arms and legs, which he had thought could be done without killing him. Dr. H. A. Grierson, medical officer of Brixton Prison, said that he did not consider Phillips insane, though he was certainly a person of abnormal mind. He was of the paranoid type but a schizophrenic was not necessarily unable to distinguish between right and wrong. The learned judge gestured in his summing up that the letters the accused had written from prison with their expression of a deliberate intention on the facts of his situation supported the evidence of Dr. Yellowlees and reminded the jury that although Dr. Grierson had wide experience of criminals, Dr. Yellowlees was a specialist in mental disorder. The jury found Phillips guilty but insane and he was sentenced to be detained during His Majesty's pleasure.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended April 23, 1938

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland Median values for the last 9 years for (i) and (b)

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for (a) The 125 great towns (123 in 1937) in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns (9 in 1937) in Northern Ireland

A dash — denotes no cases, a blank space denotes disease not notifiable or no return available

Disease	1938					1937 (Corresponding Week)					1929-37 (Median Value Corresponding Weeks)	
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)	(a)	(b)

\* 16 cases in Belfast alone

† After October 1, 1937, puerperal fever was made notifiable only in the Administrative County of London

Deaths from puerperal sepsis  
‡ Includes primary form in figures for England and Wales, London (Administrative County) and Northern Ireland

## EPIDEMIOLOGICAL NOTES

## Enteric Fever

Notifications of enteric fever in England and Wales have dropped from 29 reported last week to 21 in the week under review of these 6 belong to the paratyphoid outbreak in Cardiff where notifications for the preceding two weeks have been 10 and 2 respectively. In Scotland there was an increase of notifications of enteric fever from 5 to 14 of which 4 cases were typhoid fever and 10 were paratyphoid fever (all 10 occurred in the county of Ross and Cromarty).

## Diphtheria and Scarlet Fever

Notifications of diphtheria remained near the level of the previous week except in London where they rose from 133 to 153, of these 17 occurred in Poplar 14 in Islington 9 each in Fulham Southwark Stepney and Woolwich. A slight increase in the incidence of scarlet fever was noted from all countries except Northern Ireland where there was a small decrease. The figures for England and Wales are somewhat in excess of the median value for the last nine years while those for London are considerably less.

## Measles and Whooping-cough

In the 125 Great Towns in England and Wales there were 40 deaths from measles compared with 54 in the previous week of these 4 (14) occurred in London 4 (2) in Kingston upon Hull 4 (1) in Liverpool 2 each in Newcastle upon Tyne Plymouth and Swindon. The figures in parentheses refer to the numbers in the previous week. The average daily admissions to the LCC fever hospitals dropped from 74 to 60 while the number of cases under treatment in these hospitals on April 22 was 2,123 compared with 2,220 on April 15 and 2,241 on April 8. On the same day there were under treatment in the LCC fever hospitals 1,140 (1,140) cases of diphtheria 802 (802) cases of scarlet fever and 279 (264) cases of whooping-cough. The figures in parentheses refer to the numbers recorded in the previous week. Notifications in the eleven metropolitan boroughs in which measles is notified were for the week ended April 23 719 (734) distributed as follows: Battersea 87 (92) Bermondsey 55 (42) Finsbury 23 (39) Fulham 55 (68) Greenwich 103 (82) Hampstead 22 (24) Lambeth 158 (162) St Pancras 74 (94) Shoreditch 32 (26) Southwark 63 (60) Stepney 44 (45). The figures in parentheses denote the numbers in the previous week. In Scotland 798 cases of measles were notified compared with 724 in the previous week the figures for Glasgow were 175 (285) Dundee 295 (63) Aberdeen 190 (204) Edinburgh 74 (65) Falkirk 39 (18) Paisley 7 (25). The figures in parentheses refer to the numbers in the previous week. During the week under review there were 24 deaths from measles in the 16 principal towns of Scotland compared with 33 and 23 respectively in the previous two weeks of the 24 deaths 11 occurred in Dundee 7 in Glasgow 2 each in Edinburgh and Aberdeen. In Northern Ireland there were 16 cases of measles all in Belfast and 1 death (in Lurgan). Compared with last week there were six fewer notifications of whooping cough in Scotland and an increase of six in Northern Ireland. Deaths for the 125 Great Towns of England and Wales dropped from 21 to 16 while in Scotland there were 2 deaths (nil in the previous week).

## Vital Statistics

From the Quarterly Returns for the fourth quarter of the year 1937 which have just been published in the four

countries and which incorporate a preliminary statement for the whole of the year 1937, the following table has been compiled.

Provisional Vital Statistics for 1937

	England and Wales	Scotland	Eire	Northern Ireland
Marriage Rate per 1000 persons	1.4	7.7	8.1	6.6
Crude Birth Rate per 1000 persons	1.9	17.6	19.2	12.5
Death Rate per 1000 persons	1.4	1.7	1.3	1.1
Stillbirth Rate per 1000 births	39			
Infant Mortality Rate per 1000 live births		50	-	-

In England and Wales the natural increase in the population by excess of births over deaths was 101,200, the average annual increase in the preceding five years was 113,101. The birth rate showed an increase of 0.1 above that of 1936 being 0.5 above that for 1937 the lowest recorded. The death rate was the highest since 1920 and was 0.5 above that of 1936 and 1.0 above that of 1937 the lowest recorded. The infant mortality rate of 39 per thousand live births below that of 1936 and 1.0 above that for 1937 the lowest recorded. At 1.4 the marriage rate was the same as that for 1936.

In Scotland the birth rate at 17.6 was lower than in 1936 and the lowest recorded in Scotland with one exception. The death rate was 0.5 in excess of that of the preceding year with the exception of 1937 when the marriage rate was 7.8 and the post war year 1910-1921 when rates were abnormally high the 1937 rate of 1.7 per thousand was the highest recorded in Scotland. It is 0.6 higher than the average for the last five years. The infant mortality rate is 2.0 below that of the previous year and 0.5 below the five years average.

In Eire the marriage rate was 0.1 above that for 1936 and 0.4 above the average of 4.7 for the five years preceding. The birth rate at 19.2 showed a decrease compared with the 1936 rate of 19.6 the average for the last five years being 19.4. The death rate in 1936 was 1.4 and 1.4 for the years 1932-6.

In Northern Ireland a marriage rate of 6.64 was recorded in 1937 compared with 7.17 in the previous year the average for the preceding ten years being 6.19. The birth rate showed a fall compared with the 1936 rate of 20.3 which was slightly below the last ten years average of 20.4. The death rate was 1.1 and 1.4 in the previous year the average for the preceding ten years was 1.4. The infant mortality rate of 77 was the same as in the previous year and 1 lower than the average of the ten years.

## Typhus

During the week ended April 9 there were 20 cases of typhus in Algeria (compared with 82 in the previous week) of which 13 occurred at Algiers 33 at Constantine and 3 at Oran. In the week ended April 16 there were 10 cases of typhus in Egypt with 11 deaths compared with 107 cases and 12 deaths in the previous week. The incidence was 47 in Minufiya 23 in Aswan and 21 in Qena. In the same week in Morocco there were 23 cases and 19 deaths compared with 28 cases and 25 deaths in the previous week of the 23 cases 62 occurred in Marrakesh 35 in Casablanca 17 in Rabat 12 in Oud Zem 13 in San and 10 each in Fez and Taza. Since the epidemic of typhus began at the end of November 1937 there have been in the Marrakesh district 279 cases up to April 14 of this year of which 34 were fatal 140 of the cases have been among Europeans and of these 41 were fatal. Typhus is endemic in Morocco and tends to flare up when the resistance of the native population is reduced by malnutrition as has happened in the south following a series of harvest failures.

## Universities and Colleges

### UNIVERSITY OF OXFORD

Convocation on April 26 agreed to confer on July 16 the honorary degree of Doctor of Science upon Dr Harvey Cushing Emeritus Professor of Surgery at Harvard University, and formerly Professor of Neurology at Yale

At a Congregation held on April 28 the degree of B M was conferred on R. Roaf (*in absentia*)

### UNIVERSITY OF CAMBRIDGE

At a Congregation on April 30 a Grace was approved for conferment of the degree of Doctor of Science *honoris causa* upon Francis Peyton Rous of the Rockefeller Institute for Medical Research in New York

The following medical degrees were conferred

M CHIR—D N Matthews  
M B B Chir—\*S T Anning, A W Box, E W Dorrell, F E S Hatfield, I A C Wood  
M B—J W Parks, J G Chappel

\*By proxy

The following have been appointed University Demonstrators in Anatomy for three years: E W O Adkins, B A, and G D Channell, M B B S Lond, from April 1, 1938; F Wemyss Smith, M B Ch B Manch, from October 1, 1938

The Professor of Anatomy gives notice that applications for the Marmaduke Sheild Scholarship in Human Anatomy must be sent to the Registry on or before May 20. The award will be made towards the end of June. Those eligible are such undergraduates of not more than three years standing from matriculation and such Bachelors of Arts of not more than four years standing from matriculation who have passed Part II of the Second M B examination or done the equivalent of so passing and have also obtained honours in Part I of the Natural Sciences Tripos with Anatomy as one of their subjects. Women also are eligible. The scholarship is normally tenable for a year but a scholar may be re-elected for a second year. The emolument is £100 a year.

### UNIVERSITY OF LONDON

#### LONDON HOSPITAL MEDICAL COLLEGE

Dr Robert Hutchison, President of the Royal College of Physicians of London and consulting physician to the London Hospital, will present the prizes to the students of the hospital on Thursday, June 30.

#### LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN

The following postgraduate scholarships will be awarded for the session 1938-9:

- (a) A M Bird Scholarship £200 for one year to enable a medical graduate to obtain general experience in pathology
- (b) Mabel Webb and A M Bird Research Scholarship £200 a year for assistance in carrying on research

Further particulars and forms of application can be obtained from the Warden and Secretary of the Medical School. Applications must be received by May 22.

The following candidates have been approved at the examination indicated:

POSTGRADUATE DIPLOMA IN PSYCHOLOGICAL MEDICINE—(With Special Knowledge of Mental Diseases) G L Ashtord, Hilda M S Davidson, J Gibson, W S L Gilchrist, Augusta G Harrison, S H Lubner. Part 4: J E O N Gillespie, D Gilmour, W Telfer.

### ROYAL COLLEGE OF PHYSICIANS OF LONDON

At a meeting of the Royal College of Physicians of London held on April 28 with the President, Dr Robert Hutchison in the chair, Dr H L Tidy was elected Registrar of the College.

The following Members were elected Fellows:

Arthur Wellesley Falconer, M D Aberd (Cape Town), John Forbes Ward, M D Manch (Manchester), Stanley Graham Ross, M D McGill (Montreal), John Vernon Cannadine, Braithwaite, M D Lond (Leicester), John Edwin Mackenzie, Wigley, M B Med, Robert Cooper, M D Liverp (Liverpool), Frances Braid, M D St And (Birmingham), Cyril William Curtis, Bain, M D Oxf (Harroway), Henry Henderson Moll, M D Ronic (Leeds), Richard S J Moll, M D Belf (Belfast), William Alexander Lister, M D Calif (Albany), Cyril Lloyd Flood, M D Oxf, Henry

Brian Frost Dixon, M D Dubl, Lieutenant Colonel R A M C (Gibraltar), Julia Bell, James Gordon Danson, M D Aberd, Surgeon Captain R N (Gosport), Robert James Pulvercraft, M D Camb, Peter Henry Martin, M B Oxf, Douglas Hamilton Mackel, M B Lond, Sydney Watson Smith, M D Ed (Bournemouth), Aubrey Julian Lewis, M D Adelaide, Denis Hubert Branton, M B Oxf, Hugh Alexander Dunlop, M D Lond, Hugh Leslie Marriott, M D Lond, George White Pickering, M B Camb, Horace Evans, M D Lond, Harold Percival Himsforth, M D Lond, William George Barnard, John Clifford Hoyle, M D Lond, Archibald Gilpin, M D Lond, Ernest Thomas Conybeare, M D Lond, Soliman Azmi Pasha, M D Cairo (Egypt), John Fleming Brock, M D Oxf (Cape Town), William Drew Nicol, M B Lond (Epome), Russell John Reynolds, M B Lond, and Ram Nath Chopra, M D Camb, Brevet Colonel I M S (Calcutta).

The following were elected Fellows under B L A XXXVIII (b):

Sir Almoth Edward Wright, K B E, C B, M D, D Sc, F R S; Herbert Stanley Raper, C B E, D Sc, M B, F R S (Manchester); James Bertram Collip, D Sc, M D, F R S (Montreal); and George Richards Minot, M D (Cambridge, Mass.).

The following were appointed representatives of the College:

Viscount Dawson of Penn on the Governing Body of the British Postgraduate Medical School, Lord Horder at the Cremation Conference to be held at Oxford in July, Sir Reginald Bond on the Professional Classes Aid Council, Dr Dawtry Drenth on the Committee of Management of the Chelsea Physic Garden, Dr William Brown at the tenth international Medical Congress for Psychotherapy to be held at Oxford in July, Dr Eric Potlatch at the National Conference on Maternity and Child Welfare at Bristol in July, and Dr R R Trail at the annual conference of the National Association for the Prevention of Tuberculosis in London, June 30, July 1 and 2.

The following candidates satisfied the Censors' Board and were admitted Members of the College:

Simon Almond, M B Manch, Reginald Nevill Cudmore, Bickford, M B Adelaide, Ronald Victor Christie, M D Ed, Richard Frederick Clarke, M B Lond, Edward George Huxley Cowen, M D Lond, Christopher Sydney Darke, M B Lond, David Howard Davis, M B Camb, Antony Clifford Dornhorst, M B Lond, Bernard Freedman, L R C P, William Goldie, M B Aberd, Frederick William Gordon, M D Aberd, Ronald Douglas Green, M D Lond, John Charles Harland, M B Lond, Mohammed Ridwan Kenawy, M D Cairo, David Kendall, M B Oxf, Edwin Howard Kitching, M D Leeds, Kenneth Arthur Latter, M B Lond, Richard Edward Lecky, M B Camb, Valentine Darte Logue, L R C P, Frank Rees Magarey, M B Adelaide, Frederick John William Miller, M B Duth, Mangalore Narasimha Pai, M B Madras, Seymour Cochrane Shanks, M D Glasg, Andre Nasri Tigher, M B Cairo, Edward Wing, Twining, L R C P, Dorothy Caroline Ramia Vithayalan, M B Madras, Henry John Wade, M D Manch, Solomon Simon Yudin, M B Lond.

The Croonian Lectures on 'The Clinical Aspects of the Transmission of the Effects of Nervous Impulses by Acetylcholine' will be delivered by Professor F R Fraser at the College on May 24, 26, and 31 at 5 p m.

### BRITISH COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At the quarterly meeting of the Council, held in the College House on April 23 with the President Sir Ewen Maclean in the chair, the following were promoted to the Fellowship and formally admitted by the President:

K V Bailey, Manchester, \*W A G Gauld, Canada, W E Barrie Adshedd, Birmingham, \*J Black, South Africa, Margaret G Bolt, Nottingham, C P Brentnall, Manchester, R C Brown, London, \*R I Furber, Australia, \*J S Green, Australia, J W A Hunter, Manchester, R G Mahphand, Cardiff, \*G C Mellado, Canada, H J Malkin, Nottingham, \*S Mitra, India, \*C F Morkane, New Zealand, A L Walker, London, E Williams, London, A J Wrigley, London, \*H B Van Wyck, Canada.

The following were admitted to the Membership:

Y N Ajinkya, India, \*Mary C Albuquerque, India, J J Armistage, Salisbury, Elnor F E Black, Canada, Doris B Brown, Harrogate, W D Brown, London, H Canwarden, Guernsey, \*W D Cunningham, Australia, Mary Evans, Manchester, M B Hallam, Manchester, \*O S Heyns, South Africa, \*R A Leach, India, J C Loxton, Australia, \*B E Meek, Canada, J M P Greenock, \*E A Menon, India, \*E B Moore, Australia, P W Nichol, London, Susanne J Paterson, Edinburgh, C G Rowan, Aberdeen, P W S Riley, Australia, \*D F Standing, South Africa, L M Snaith, Manchester, Dorothy M Stewart, New Zealand, R K Tampan, India, R A Tennant, Cambuslang, \*G A Thompson, Australia, W H Tod, Leeds, \*C V Ward, Canada, Alice Woodhead, London, J C Whyte, Canada.

\*In absentia.

The following were elected to the Membership: F G MacGuinness, Canada, G J Strain, Canada, Thomas Norman Arthur Jeffcoate, M D, F R C S D, MCOG, and Richard Alan Brews, M D, M S, F R C S.

MRCP MCOG have been appointed the next Blair Bell Memorial Lecturers

At the annual general meeting of the College held on April 25 in the College House with the President, Sir Ewen Maclean in the chair the following were elected to the Council in place of those retiring by statutory rotation *Representatives of the Fellows* Mr A W Bourne Professor A Levlard Robinson Professor William Gough Professor James Hendry *Representatives of the Members* Mr E A Gerrard Mr W C Armstrong

## Medical News

Dr Herbert Birkett (Montreal) Dr Brown Kelly (Glasgow) Dr D R Paterson (Cardiff) and Dr StClair Thom on have been elected Honorary Members of the Gesellschaft Deutscher Hals-, Nasen- und Ohrenärzte

The annual meeting and luncheon of the Tavistock Clinic (Malet Place W.C.) will be held at the Cafe Royal Regent Street W. on Monday May 9 at 1 p.m. The speakers will be the Earl of Faversham Parliamentary Secretary to the Minister of Agriculture and Fisheries Mrs I M Sieff and Dr J R Rees, medical director of the Clinic

The following meetings of the Tuberculosis Association will be held at 26 Portland Place W. on Friday May 20 4 p.m. council meeting 5.15 p.m. general meeting papers on Trauma and Tuberculosis by Dr J Browning Alexander Dr G J Johnstone and Mr C A Collingwood 8.15 p.m. papers on Anaesthetics in Thoracic Surgery by Dr J T Hunter and Mr J B Hunter

The next clinical meeting of the Society of Radiotherapists will be held at 11 Chandos Street W. on Friday May 20 at 5 p.m. when the subject for discussion will be Radiotherapy of Brain Tumours. The opening speakers will be Prof. or Hugh Cairns Mrs E L M Hilton and Mr R McWhirter

The annual general meeting of the British Institute of Radiology (incorporated with the Röntgen Society) will be held in the Reid Knox Hall 32 Welbeck Street W. on Thursday May 19 at 6.30 p.m.

H.R.H. the Duchess of Kent will open the new maternity wing of the Livingstone Hospital Dartford on the afternoon of Wednesday May 18

The twenty fourth Annual Conference of the National Association for the Prevention of Tuberculosis will be held in the Great Hall of the British Medical Association House Tavistock Square W.C., on June 30 and July 1 and 2 and will be preceded by the annual meeting of the care committees in the morning of June 29. Invitations and further particulars will be issued in due course

The eleventh Congress of the Society of Oto-neuro-ophthalmology will be held at Bordeaux from June 7 to 9 under the presidency of Professor Portmann when the subject for discussion will be haemorrhages in oto-neuro-ophthalmology. Further information can be obtained from the general secretary M Auguste Tournay 38 Rue de Vaugirard Paris XVI

In our advertisement columns this week the British Empire Cancer Campaign invites applications from male British subjects for the post of Medical Secretary and Registrar to the Clinical Cancer Research Committee. The appointment is a whole time one and remuneration will be at the rate of £10 per annum. Applications should reach the general secretary of the Campaign at 11 Grosvenor Crescent London SW 1 by June 10

The first French Congress of Good Bread will be held in Nice on May 14 and 15. Further information can be obtained from the general secretary M Robert Septimier 16 Rue de l'Hotel des Postes Nice

The seveneenth International Neurological Retreat will be held in Paris on May 31 and June 1 at La Salpêtrière 47 Boulevard de l'Hôpital. The subject for discussion will be the pupil in neurology. During the conference a demonstration will be given of the work of Dejerine Barthez and Charcot. Inquiries should be addressed to Dr Croizier 70 bis Avenue d'Iena Paris XVI. The programme will be sent to those who notify their intention to attend

The sixteenth international postgraduate course of the Vienna Medical Faculty will be held from May 16 to 25 in subjects being diseases of the digestive system and diseases of the endocrine gland. The fee is RM 2. There will be radiographic demonstrations illustrating the lectures and clinical work. Further information may be obtained from the office of the International Postgraduate Course, The University of Vienna. The demonstrations and lectures will take place in various hospitals and clinics

In our advertisement columns this week the Middlesex County Council invites applications for the post of pathologist to the Central Middlesex County Hospital, Acton Lane Willeiden NW, at a salary of £1100 per annum with 10 annual increments of £20 to £1200 per annum

Dr William Brown who was recently chosen prospective Liberal candidate for Oxford City has now resigned this position. He has found that it is no possible to combine activity in party politics with his work as a medical psychologist in London and as Director of the Institute of Experimental Psychology in Oxford University

The March issue of the *Bulletin de l'Organisation d'Hygiène Publique* in addition to a sympathetic notice of Sir Thomas Stanton, who was the delegate of the British Colonies on the permanent committee of the League of Nations, contains papers on quarantine regulations in Italy in the United States sanitary conditions in the United States in the French Colonies disinsection of ships at Khartoum prevention of rabies in Italy vaccination of cattle in Poland anthrax in Czechoslovakia recent developments in the purification of water in the United States and vaccination in the prophylaxis of venereal diseases in the Argentine Republic

The March issue of the *Scottish Geographical Magazine* opens with an interesting article entitled Australian Impressions by Dr Douglas Guthrie of Edinburgh

A third edition has now been issued of *Air Raid Precautions Handbook No. 2* which deals with first aid and nursing for gas casualties. It is published for the Home Office by H.M. Stationery Office at 4d.

To commemorate the centenary of John Shaw Billings the New York Academy of Medicine and the New York Public Library recently held exhibitions of his work and his versatility in various reference was made in this journal on April 9 (p. 796)

The well known paediatric Gen. Rat P. C. A. Ad. C. Czerny of Berlin was awarded the medal of merit of the German Reich for the discovery of the causative agent of diphtheria

There has recently been a small outbreak of typhoid in Vienna chiefly affecting the lower classes

A Chinese Dermato-logical Society has recently been founded with Prof. C. F. K. Chen as president

*On re-reading the article to which Dr Basman refers one can only conclude that he has in mind harmful results which were encountered when the sodium lactate treatment was being evolved, and has overlooked Dr Hartmann's statement that when he took to using dilute solutions (1/6 molar) these harmful effects were eliminated*

Dr E E MAILLS (Jersey) writes With reference to your annotation in the *Journal* of March 19 (p 629), I would like to relate the following experience In 1907, when in Nigeria, I saw a patient who was suffering from the worst attack of gonorrhoea that I have ever seen With infection of six months' standing he had a blood stained purulent discharge, a perineal fistula consequent upon a perineal abscess, pain in his joints, and a wretched general condition I cabled home for a supply of anti gonococcal serum, on its arrival the contents of one phial were injected into the patient's axilla I cannot remember after this lapse of time whether it was 10 ccm or 25 ccm This was about 4 pm one afternoon I saw the patient next morning about 8 am when he declared that he was cured This statement was almost, but not quite, true The fistula had certainly healed during the night, the joint pain had disappeared and so had the discharge, except for what subsequently turned out to be a 'morning drop' It seems an incredible story but I can only assert that it is true A few months later, on my arrival in England, I mentioned the case to a physician who is now one of the leaders of the profession He said 'Very interesting' I am the man who injected the donkey with gonococci for Burroughs Wellcome and what I would like to know is if normal horse serum would have been equally effective'

## Maida Vale Hospital for Nervous Diseases

The Hospital for Epilepsy and Paralysis and Other Diseases of the Nervous System has changed its name to the Maida Vale Hospital for Nervous Diseases. It was founded in 1866 under the title of the London Infirmary for Epilepsy and Paralysis. Soon after its foundation so many inquiries were received from county districts as to whether the benefits of the hospital were confined to London patients that in 1868 the title was changed to the Infirmary for Epilepsy and Paralysis. The name was again changed in 1873 to the Hospital for Diseases of the Nervous System but in the days such a title apparently did not convey to both medical and lay minds the functions of the hospital and in 1875 the name was again changed to the Hospital for Epilepsy and Paralysis and Other Diseases of the Nervous System and the hospital was incorporated in 1900 under that name.

### Relief of Distress in Madrid

**Relief of Distress in Madrid**

Through the Bishop of Gibraltar the Save the Children Fund has received an urgent appeal from the Scottish Women's Ambulance Unit in Spain, from which it appears that the relief work carried out by the Unit is in desperate need and that stores are practically exhausted. There are also hundreds of new applications each case more tragic than the last. We implore your help. Gifts towards providing the necessary aid will be welcomed by the Save the Children Fund at 20 Gordon Square London WC1. They should be earmarked Madrid.

## Medical Golf

**Medical Golf**  
The Medical Golfing Society held its Spring Meeting at Princes, Sandwich on Saturday April 30, and Sunday May 1. The result of the Captain's Prize was T H P Kolesar (3 down) Douglas Craig (4 down) the Green was won by H Chapple and W Dale the President's Prize was won by A Galletly (75) after a tie with Michael Smith and Douglas Craig T H P Kolesar also won the 9 holes concealed

## Disclaimer

**Disclaimer**

Dr G W Morry (Shrewsbury) writes On April 26 a short paragraph appeared in a London daily paper giving details of an intended motor tour shortly to be undertaken by me, my wife and myself. This paragraph gave a very false impression of a self inserted advertisement in bad taste. We should like to make it known that this paragraph was printed without our knowledge or consent.

## QUERIES AND ANSWERS

### Acute Sleeplessness

M H writes Can any of your readers suggest a remedy for acute sleeplessness in an otherwise healthy man of 74? The cause in the first place was acute business worry. Barbiturates excite and milder sedatives appear useless. Omnopon, by injection, works well, but orally the effect lasts only for two to three hours. Paraldehyde excites to an extreme degree.

## An Internal Sanitary Pad

X Y X writes in reply to "Woman Doctor" (April 23, p. 932) My experience has differed from hers in that I and a number of my colleagues and patients have found an internal sanitary pad to be far more comfortable and convenient than any other kind. The feeling of fullness and stimulation in the vagina does not arise if the pad be pushed well inside so that it does not come in contact with the hymen. I have found that the most convenient form of pad is a firm cylindrical roll of cotton-wool which can be removed and dropped into the lavatory pan before defaecation thus obviating any inhibition of complete defaecation such as 'GP' mentions. I have also found that intelligent virgins—for example, medical students—can quite well use these pads.

**LETTERS, NOTES, ETC**

### Sodium Lactate for Diabetic Coma Corrigendum

**Sodium Lactate for Diabetic Coma**

In the *Journal* of March 26 there appeared an annotation on the treatment of diabetic coma by the use of racemic sodium lactate and certain criticisms of this annotation were made by Dr J Basman in the *Journal* of April 9 (p 814). In case readers may be confused we should perhaps make some reply to Dr Basman's criticisms. It is quite true that Dr Hartmann now omits the dextrose and gives only sodium lactate solution and insulin to cases of diabetic coma but this was not clear in the article commented on in the annotation—in his footnote to the article which forms the subject of the annotation it is plain that dextrose was recommended. According to the footnote he gives sodium lactate as well as dextrose according to the tables and charts dextrose was omitted. Hartmann's subsequent work makes it clear that dextrose is omitted. The second criticism implied by Dr Basman is in the sentence "In view of the suggestion as to the meagre possibility of harmful effects in the administration of sodium lactate I should like to refer to the thirty cases published in the above journal." This sentence implied that the possibility of harmful effects is not meagre.

### 370 Pleural Effusion after Pleurolysis

O M MISTAL (*Tubercle* January 1928 p 145) states that pleural effusion is the commonest complication following pleurolysis. The exudates are large in 10 per cent of cases only. Their importance is that they produce toxæmia, anorexia, fever and loss of weight; they may also reactivate latent lesions in the opposite lung. They are usually due to thermic irritation and the liberation of bacilli. The most frequent effusions are seroh fibrinous; they may occur from a few days to a few months after operation. Prognosis depends on the strength of the patient on his reaction on the type of infection and on its virulence. Aspiration of the exudate and replacement by air is indicated when the effusion is not increasing; pleural wash outs with saline or distilled water are helpful. Thoracoscopy is indicated when the effusion persists in spite of treatment. Haemorrhagic effusions are nearly always caused by bad technique; they have little tendency to coagulate. They should be evacuated as soon as possible to avoid their transformation into empyemas. Empyemas are becoming rare; the prognosis is worse the more rapidly they come on and wash outs are specially indicated. Oleothorax sometimes gives good results. The author advocates direct irradiation of the pleural cavity with ultra violet rays. Weak doses are used so as not to irritate tissues already affected; this therapy must only be used however in cavities already opened. Pulmonary fistulæ which keep up an empyema must be searched for. Empyemas may be prevented by avoiding refills at a high pressure which breaks the fibrinous basal membranes. In severe cases permanent drainage is the only efficacious procedure. Attention to general hygiene and to the diet is essential in all cases. Examination of the effusion reveals its nature and indicates the kind of treatment required. At the beginning of a pleurisy the polymorpho-nuclear leucocytes are replaced by lymphocytes; eosinophilia is a defensive reaction and is only found in non-infected exudates; lymphocytes and macrophages indicate the tuberculous character of the effusion.

### 371 Pemphigus

A E H BINGER (*Wien klin Wschr* February 25 1938 p 237) discusses a fatal case of pemphigus in a young Jewess of 27. She had a severe attack of furunculosis involving both axillæ and was treated with injections of a staphylococcal vaccine (fourteen doses). Shortly afterwards she developed a symmetrical eruption of vesicles the size of hemp seeds and filled with a clear fluid on both thighs. Then bullæ the size of walnuts appeared on the back and abdomen and were also roughly symmetrical. There was no irritation, pain or pruritus and the bullæ disappeared spontaneously after a short time but new ones continued to make their appearance. They were unilocular, not very distended and showed a tendency to collapse; they contained a viscid clear amber fluid. The patient was treated by injections of the fluid contained in these bullæ but this did not arrest the process. The bullæ increased in size and the fluid in them became more and more viscous. The walls of the bullæ were also tougher so that whereas at the start they could be pricked with a pin they now had to be cut open with scissors. Numerous vesicles next made their appearance simultaneously on both eyelids; they only persisted for fifteen to thirty minutes after which they turned into reddish crusts. Similar crusts appeared in the nares almost stopping up the nose and obliging the patient to breathe through her mouth. A rabbit which had received a subdural injection of the content of one of the earlier vesicles died of cachexia accompanied by paresis and convulsions.

The patient was given a course of injections with an emulsion prepared from the brain of this rabbit. No further bullæ appeared after the second injection. The spine of this patient grew steadily worse; extensive serpigulous undermining of the epidermis began and was accompanied by fever, the ulcerated surfaces were extensive and altogether the patient's condition became one of extreme misery. She died seventeen days after the onset of the undermining process; the temperature reached 106° F just before death. The author does not commit himself with regard to the ætiology of this case but suggests that it may have been due to the vaccine reaction of the original tuberculosis. Pemphigus has been known to follow vaccination and also the administration of antitetanus serum.

### 372 Lumbago

J NICOLAYSEN (*Nord med Tidsskr* February 26 1938 p 321) points out that in Norway rheumatic lumbago is dealt with under sickness insurance whereas traumatic lumbago under accident insurance. Between 1928 and 1934 696 cases coming under sickness insurance had led to the average duration of incapacity was fifteen days whereas it was between thirty three and thirty four days for 102 cases of traumatic lumbago; for cases of pure traumatic lumbago the average was seventeen days. He has investigated the 944 cases of lumbago in connection with which applications were made for accident insurance benefit in 1934. Only 502 of the 944 claims were accepted; rejection of the remaining 442 cases depended on the examiner's opinion that the incapacity for work was not due to any accident but had arisen under ordinary conditions of employment. It was held that the lumbago was rheumatic in several of these cases. Discussing the differential diagnosis of traumatic and rheumatic lumbago the author points out that the condition cannot be regarded as traumatic simply because the person concerned has suddenly had to discontinue work for this is often the case with rheumatic lumbago whereas traumatic lumbago may give rise to violent pain only after several hours. This was so with as many as seventy six of the patients whose lumbago was finally diagnosed as traumatic and twenty of these patients could still work on the day after the accident. Of importance in differential diagnosis is the history of previous attacks for while such a history is characteristic of rheumatic lumbago it is very rare in traumatic lumbago.

## Surgery

### 373 Peripheral Vascular Disease

W S COLLENS and N D WILENSKY (*J Amer med Ass* December 23 1937 p 2125) describe the results obtained in the treatment of 124 cases of peripheral vascular disease by intermittent venous occlusion. It was found that the temporary interruption of the venous return results in increasing arterial amplitude and that the cause of the obstruction is followed by a pronounced reaction in the hæmia. These principles were applied in the treatment of peripheral vascular disease by means of an apparatus which automatically produced intermittent pressure on the venous compression. The apparatus was connected to a pneumatic cuff which embraced the proximal part of the extremity and was inflated to the pressure necessary to constrict the veins and was then released. It was found that compression up to 80 mm Hg for 15 to 20 minutes with release for 10 minutes was applied continuously for as much as 15 days and had a definite therapeutic effect in cases of disease associated with pathological arterial changes. In the cases reviewed the average twenty seven cases of thromboangiitis obliterans. The

# EPITOME OF CURRENT MEDICAL LITERATURE

## Therapeutics

was complete relief of pain in 85 per cent of cases within forty eight hours, and of seventeen cases presenting ulcers twelve healed completely. There were thirty-three cases of arteriosclerosis obliterans, complete relief of pain was obtained in the same period of time in 82 per cent of cases. Four chronic indolent ulcers healed completely. Arteriosclerosis obliterans associated with diabetes was treated in forty eight cases, 60 per cent of these were free from pain after forty eight hours and 33 per cent were partially relieved. There was complete healing of open lesions in 76 per cent of cases, the remainder needed amputation. Seven cases of embolus and acute arterial thrombosis showed relief from pain within eight hours, and in a further seven cases chronic varicose ulcers of long standing were healed.

## Tuberculosis of the Breast

374 V CONTINI (*Arch Ital Chir* December, 1937, p 601) gives an account of his experimental work in connexion with tuberculosis of the breast. This disease would not appear to be so rare as was once thought, it is more common in the female but may also occur in the male. There is little agreement as to pathogenesis. The mode of spread to the breast may be direct, haematogenous, of lymphatic or by the milk ducts. Contini inoculated twenty eight guinea-pigs in various stages of sexual activity (rest pregnancy, lactation) with an emulsion of human tubercle bacilli. This was injected into the groin, or into the internal jugular vein. The animals were killed at different intervals of time and the breasts, lungs, liver, spleen and kidneys examined. As a result of his investigations the author comes to the following conclusions. Only direct injection or injection into the milk ducts gave positive results. Intravenous injection only gave positive results when the injection was in a state of functional activity. Injection into the lymphatics was invariably negative, thus rendering the possibility of a retrograde infection of the breast by the lymphatics very doubtful. Pregnancy, lactation, and trauma all favour the development of the infection. Tuberculosis of the breast does not remain localized, but is constantly followed by a general infection of the other organs. Primary tuberculosis of the breast arises only when the infection took place directly or by the milk ducts, in all other cases mammary tuberculosis is a secondary phenomenon. The giant cells seen in this condition would seem to be usually of parenchymal origin from the acini of the glands, and only rarely of epithelial origin.

## Giant cell Tumours of the Spine

375 G E RICHARDS and A C SINGLETON (*Radiology* January, 1938, p 43) report three cases of giant cell tumours of the spine and discuss the diagnosis pathology and treatment of these tumours. The condition is sometimes referred to as myeloma or myeloid sarcoma but according to the Bone Registry Committee of the American College of Surgeons these neoplasms are of a benign nature. The majority of cases occur in the latter half of the second and in the third and fourth decades. The spine is the seat of the lesion in about 8 per cent of all cases of benign giant cell tumours. Radiographically the tumour may appear as a well delimited or less frequently as a diffuse lesion. The tumour may originate in any part of the vertebra and extend by direct spread to the adjacent vertebrae and tendons for pedicles and transverse processes to be involved. The intervertebral disk is usually left intact even though a whole vertebra may be involved. The response of these tumours to x-ray treatment is slow, and is often preceded by a stage of lysis and apparent extension of the disease which is followed by bone regeneration and repair but in the author's opinion irradiation is still the treatment of choice.

10.9.38

## Cryptorchidism and Hypogonitalism

376 W O THOMPSON, N J HECKEL P K THOMPSON and L F N DICKIE (*Endocrin*, January, 1938, p 59) state that further investigations have confirmed the value of the anterior-pituitary-like principle in the treatment of undescended testis and hypogonitalism. In patients who had not undergone surgical treatment descent was produced in eight of thirty-six undescended testes (22 per cent) in twenty-eight patients, varying in age from 1 to 37 years. In cases in which surgical procedures had failed descent was effected in three out of six patients with undescended testes, and in one-third the growth was marked. In three boys of 4, 7, and 9 years of age premature puberty was produced. In the case of a boy aged 7 the penis grew to adult size, the prostate enlarged, a luxuriant growth of pubic hair developed, a small amount of hair appeared on the face, and the pitch of the voice changed. Marked growth of the genitals may occur without descent of the testes. Premature puberty may be avoided if administration of the principle is not prolonged. In successful cases descent occurred within nine weeks, and harmful results were rarely noted in this length of time. Growth of the genitals was produced in nine out of twelve cases of hypogonitalism, the patients were mainly of the Frohlich type.

## Fever Therapy in Gonococcal Infections

377 T G SCHNABEL and F FETTER (*Amer J Syph*, January 1938, p 39) claim that the value of fever therapy has been definitely established in the treatment of gonococcal infections, particularly arthritis. They report their results in the treatment of 136 patients. The Kettering hyperthermia was used, it is an air-conditioned cabinet. The usual session is one of six hours (five for the first treatment) during which the body temperature is kept at between 106° F and 107° F (rectal). Of fifteen girls with gonorrhoeal vaginitis thirteen were cured and two improved. Two women with acute pelvic inflammatory disease and gonococcal origin were cured. Of four men with genital complications of gonorrhoea two were cured and two improved. Of seventy patients with acute gonococcal arthritis forty eight were cured and twenty two were proved. Of twenty-three patients with chronic arthritis six were cured and seventeen were improved. As compared with other types of treatment, fever therapy shortens the period of hospitalization and improves the prognosis. So far, the authors have found no case of gonococcal infection which has not responded in appreciable degree to adequate fever therapy.

## Succinic Acid in Diabetic Acidosis

378 According to A BROCKMULLER (*Munch med Woch* February 18, 1938, p 252) succinic acid was found by Baer and Blum in 1911 to diminish the excretion of acetone bodies in the urine in diabetes. Recent observations show that it is of importance in carbohydrate metabolism, in the fixation of hepatic glycogen, and in anaerobic cell metabolism. Three cases are described of diabetic acidosis resistant to sodium acetone, bicarbonate, hydrate, and insulin treatment in which acetone bodies disappeared from the urine after the administration of 0.5 to 2 grammes daily of succinic acid. There is a small coincident rise in the blood sugar concentration and succinic acid does not diminish the necessity for insulin. If the metabolic dysfunction responsible for the acidosis has been sufficiently protracted to do irreparable toxic injury to tissue cells succinic acid is without effect, hence it is suggested the negative results of English and Austrian investigators.

## Neurology

## 379 Rare Forms of Neurosyphilis

D. PAULIAN (*Wien klin Wschr* February 11 and 18, 1938 pp 161 and 197) draws attention to a number of rare forms of syphilis of the central nervous system. Syphilis may be the cause of nearly all nervous affection. In the mid and hind brain it may cause but more frequently simulates epidemic encephalitis. Undoubted proof of syphilis as an aetiological factor in the production of Parkinson's syndrome exists. Syphilitic pseudo bulbar paralysis has also been observed. The pituitary may be affected producing symptoms which include narcolepsy, polyuria, thirst, obesity and amenorrhoea. In contrast to these obese patients those affected by the dysphagic type of cerebral syphilis are very thin. The cerebellum is rarely affected by syphilis; syphilis may however, produce cerebellar atrophy. Friedrich's ataxia, and very seldom cerebellar gummata. Epilepsy has long been known to occur in subjects with hereditary syphilis. In recent times the existence of syphilitic psychoses has been stressed. The spinal cord and its coverings may be attacked by syphilis giving rise to spastic spinal paralysis, amyotrophies and meningo-myelitis. Syringomyelia and multiple sclerosis may be simulated but the author states that a true syphilitic multiple sclerosis does not exist. Syphilis of the nerve roots gives rise to motor and sensory disturbances, pain resembling sciatica and loss of sphincter control. It may also produce well marked syndromes—for example, Dejerine Klumpke, Korsakoff and Guillain Barré syndromes. Attention is drawn to latent syphilis of the central nervous system which occurs in two forms—one which may disappear spontaneously and one which is but a precursor of later and more clearly defined manifestations; the differential diagnosis is often difficult.

## 380 Spinal Arachnoiditis

W. F. SUERMONDT (*Zbl Chir* March 12, 1938 p 581) reviews the surgical treatment of spinal arachnoiditis. The underlying lesion is the formation of scar tissue in the subarachnoid space which may directly compress the cord and nerve roots or lead to the formation of arachnoid cysts. The trouble always begins and is more marked in the dorsal part of the space, the anterior portion is affected later. Stookey assumes that in addition to the obvious mechanical effects such adhesions interfere with the normal horizontal pendular movements of the cord which are supposed to occur as a result of the respiratory waves in the cerebrospinal fluid. Minute recurrent traumata are produced in this manner and also the fixed cord is exposed to injuries during excessive movements of the spinal column. The diagnosis is based on clinical evidence supported by the demonstration of a block to the passage of lipiodol. The descent of the lipiodol should be watched on the fluorescent screen while the patient is gradually tilted on the table. Partial blocks can then be seen and immediately photographed. The discrepancy between severe pains which the patients complain of and the relative scarcity of objective neurological signs is characteristic. Treatment is surgical in all but the very early cases in which conservative measures may be tried. Operation must not be deterred for too long for permanent structural changes may take place in the cord and widespread adhesions will greatly increase the difficulties of the operation. After suitable exposure the cord and nerve roots are carefully and completely freed so that at the conclusion of the operation compression of the jugular veins will produce a free flow of cerebrospinal fluid. The author advises against closure of the dura to prevent the reformation of adhesions. In sixteen cases treated by the author a history of trauma was obtained in six, and severe infections had preceded the

onset of arachnoiditis in another six patients. No case could be found in the remaining four. The results of operation was completely satisfactory in six cases, five were improved and three showed no improvement. In the last group the disease had progressed to such structural changes in the cord. Two of the sixteen patients died.

## 381 Disseminated Sclerosis

G. TANFANI (*Mitt. d. med. March 3, 1938 p 223*) records forty cases of disseminated sclerosis in patients aged 10 to 22 to 52 treated by the production of an aseptic meningitis. The aseptic meningitis was brought about by giving three or four intrathecal injections of 0.5 c.c. of distilled water at intervals of two or three days between each injection. The aseptic meningitis is believed to stimulate the nervous system generally. Of the 40 cases 30 were treated, most of which were cases of long standing, eighteen proved refractory while all the others showed a varying degree of improvement.

## 382 Insulin Shock Treatment of Schizophrenia

B. VAN DINTHOP and E. JANSSEN (*Nederl. Tijdschr. Geneesk.* March 12, 1938 p 1264) record the observations on forty-two cases of schizophrenia in patients aged from 19 to 90 treated by Sakel's method of intravenous injection of insulin. Their results accord with those of previous writers. The treatment gave encouraging results in recent cases although a reliable conclusion as to the nature of the remissions cannot yet be drawn. Of the forty-two cases thirteen were cured or showed considerable improvement and five some improvement. In twenty-three patients there was no change.

383 G. RYLANDER (*Hygien. Stockh. Febr. 28, 1938 p 97*) calculates that about 70 per cent of all the beds in Swedish asylums are occupied by schizophrenics but that only 20 to 25 per cent of the admissions represent early cases. Much would therefore be gained if in some 50 per cent of these early cases treatment could be so effective that it prevented the development of chronic schizophrenia. The author has compared the proportion of spontaneous recoveries recorded in the literature with that effected by insulin shock treatment. At least temporary recovery occurs spontaneously in about 1 per cent of cases. The proportion of recoveries following insulin shock treatment is much higher and according to the authors nearly 60 per cent. The comparison is all the more favourable to insulin shock treatment because successes are achieved in a much shorter time. According to the literature the mortality from this treatment is between 1 and 2 per cent. At the author's hospital treatment has been completed in seventeen cases, eleven of which represented good remissions. In the two others some improvement could be noted. Of the nine patients still undergoing treatment seven appeared to benefit from it.

## 384 Rate of Blood Flow in Schizophrenia

L. E. FINESINGER, M. E. COHEN and A. J. TAYLOR (*Arch. Neurol. Psychiat.* Chicago, January, 1938 p 24) record a study of the blood flow in fifteen cases of schizophrenia. They were not able to confirm Fineman's conclusions. They found no abnormal slowing of circulation. In a series of determinations of circulation by the cyanide method the average arm circulation circulation time was 14.9 seconds with a range of 11 to 26 seconds, these being within the normal limits. The average pulmonary circulation time was 10.5 seconds, the range being from 9 to 16 seconds. In a series of thirty-one patients with schizophrenia the average arm circulation time was 8.4 seconds, the range being from 7 to 11 seconds, all these figures lie within the normal limits. The authors state that the only marked abnormality

78 MAY 7 1938

## EPITOME OF CURRENT MEDICAL LITERATURE

during basal conditions and that their data consequently give no information about the comparative circulation times during basal and non-basal conditions. They are unable to explain the discrepancy between their results and those in Freeman's experiments, in which the mean pulse rate reported was 58 beats a minute, their own findings during fasting periods averaging 82 beats a minute—a difference they remark, which might contribute towards explaining the divergence, since there is a negative correlation between the pulse rate and the circulation time. The results recorded by the present authors do agree with those obtained by Freeman, however, in indicating a lack of correlation between the circulation time, the subject's age and the systolic and diastolic blood pressure readings.

## Obstetrics and Gynaecology

## 385 Antefixation of the Uterus

J. NOVAK (*Zbl Chir* February 26, 1938, p. 467) states that subjective symptoms attributed to mobile uterine retroflexion are only rarely caused by it, operation is unjustified unless temporary correction of the malposition by means of a pessary causes pain to disappear or very considerably improve. Of operative treatments the safest, provided antefixation as the most effective and the safest, provided attention is paid to certain technical points. (These eliminate the possibility of post-operative ileus and prevent the occurrence of pain near the point of fixation of the round ligaments in the anterior aponeurosis of the rectus). They consist in (1) formation of a new, not unduly deepened vesico-uterine excavation, by choosing for fixation of the round ligament a point not too near its uterine end, and by drawing out the ligament abdominal ring, (2) careful closure, by suture, of the loop made by the lateral abdominal part of the ligament, and (3) fixation of the round ligament loop to the posterior wall only of the anterior sheath of the rectus.

## 386 Haemorrhage in Extra-uterine Gestation

F. DRAZANCIC (*Zbl Gynak* February 12, 1938, p. 344) points out that ectopic gestation may give rise to few or no symptoms and be very difficult to diagnose. He agrees with other authors however, that a differential diagnosis between uterine haemorrhage due to extra-uterine pregnancy and that due to ovarian or inflammatory causes can be made even in cases in which vaginal examination appears to reveal nothing abnormal. Injections of hypophysis once or twice daily on successive days, or the intravenous injection of the patient's own blood, practically always brings about a cessation of uterine bleeding due to ovarian or inflammatory causes. Such injections never have any effect on haemorrhage due to extra-uterine pregnancy.

## Glandulo-cystic Hyperplasia

E. DAHL-IVERSEN and HJOERDIS-JOERGENSEN (*Lyon chir* November-December 1937, p. 659) point out that patients suffering from glandular hyperplasia of the endometrium have persistent follicular cysts in one or both ovaries, and that the disease is due to the action of the folliculine on the endometrium causing menorrhagia. It has been found that the condition responds to treatment by standardized gonadotropic hormone and gives the best results. Treatment of cystic glandular hyperplasia must be made to find the preparation which is necessary for both therapeutic and therapeutic purposes. Curettage is therapeutically more successful in older women than in the younger or middle-aged. In cases where recurrence takes

place after curettage hormone therapy is indicated. Good results have been obtained in young women treated with luteinizing hormones. It has also been found that by the administration of gonadotropic hormone, especially with prolactin, it is possible to bring about ovarian modifications such as maturation of the follicles, haemorrhage into the follicles, and luteinization. Details are given of the various preparations which may be used, four cases are described in which hormone therapy was successfully carried out.

## Pathology

## 388 Nicotinic Acid in Dietary Deficiency

H. CHICK, T. F. MACRAE, A. J. P. MARTIN and C. J. MARTIN (*Biochem J* January, 1938, p. 10) report the effects of administering nicotinic acid to two pigs fed on a maize-peameal-casein diet deficient in vitamin B. Both animals were losing weight rapidly, had diarrhoea and dermatitis were refusing food, and were so ill as to be expected to die within two to three days, one had a paresis of the hind limbs. Various fractions of yeast extract had no effect. Nicotinic acid was given first intramuscularly in doses of 100 mg, and then by mouth in doses of 60 mg a day. Within twenty-four hours of the first injection appetite returned and there followed a steady reversal of the former condition, so that after six weeks treatment the pigs appeared quite healthy. Experiments are being conducted to ascertain the daily requirement of nicotinic acid on the basal diet used.

## 389 Sero-vaccination against Typhus

R. WEIGL (*Arch Inst Pasteur, Tunis* December 1937, p. 665) points out that both in guinea-pigs and in man in attack of typhus may be prevented, or modified, after infection by louse-bites if passive immunity is induced by the administration of convalescent serum. Such immunity is temporary, and should be reinforced by active immunization by the phenolized rickettsia-vaccine. Serum from convalescents is not always readily obtained, especially at the beginning of an epidemic. Weigl has found that it may be replaced by the serum of persons recently vaccinated with his protective rickettsia vaccine; this serum, he finds, is equal if not superior to that of convalescents in protective power and antibody concentration.

## Milk Bottles

## 390

J. MARTIN SANSBY (*Arch Pediat*, January, 1938, p. 22), in a study of milk bottles with metal caps, points out that the sealing of the bottle to prevent leakage is not in itself sufficient to prevent contamination of the milk. To ensure completely against this the cap should cover the entire pouring surface. The bottle itself should be so constructed that in the act of pouring it will prevent the milk from coming in contact with any uncovered part around the opening of the bottle which may be contaminated during the pouring. This fact was proved by swabbing the surface of bottles allow the milk to be contaminated during pouring. From this bacteriological study it is shown that many types of bottles below the cap with *B. coli* and caps of different designs were tried and are illustrated in this paper. The best bottle and cap are described, and the author thinks that this type should become universal. It is important that the bottle be so designed that the milk when poured will come in contact with, and only with, that portion of the glass which has been covered by the cap. It is also important that if the cap is loosened or removed during the course of delivery it should not be capable of manual replacement.

## Pure, active, comfortable and inexpensive

An increasing tendency is shown to claim a very high purity and remarkable hæmopoietic potency for injectable fractions of liver

Independent chemical research in stringent conditions of clinical test have maintained the place of Organon's PERNAEMON FORTE in this field

PERNAEMON FORTE, now a clear solution provides a medium for the therapy of Pernicious Anæmia as pure as active as comfortable and as inexpensive as any available.

## ‘PITUITRIN’

### THE ORIGINAL EXTRACT OF THE POSTERIOR PITUITARY GLAND

INVESTIGATIONS on pituitary (posterior lobe) extracts began in the Parke-Davis Research Laboratories about 38 years ago. As early as 1905 extracts were submitted to experimental laboratory and clinical trial for their blood pressure raising action. Subsequent to the discovery of the oxytocic property of posterior pituitary extracts the first preparation to be made generally available to the medical profession was introduced under the name ‘Pituitrin’ in the year 1908.

Since its introduction ‘Pituitrin’ has been assayed on both its oxytocic and blood pressure-raising properties, and the strength has remained the same as that which was subsequently adopted as an international standard and designated 10 International units per c.c.

As a result of further investigations Parke, Davis & Company announced in 1927 the separation of two active constituents from ‘Pituitrin’. These are available under the names ‘Pitocin’ (the oxytocic principle) and ‘Pitressin’ (the pressor and anti-diuretic principle).

Parke, Davis & Company can claim an experience of more than thirty years in the manufacture of posterior pituitary extracts, an experience that is unique and enables them to offer preparations that are unsurpassed for uniformity of strength, reliability of action, and freedom from excess proteins.

## Why Lactogen so adequately replaces Breast Milk where natural Feeding is deficient or impossible

Scientifically and in actual practice, Lactogen resembles Baby's natural food as closely as is possible. Both the proportions of its food elements and its physiological character are practically identical. The homogenisation process reduces the fat globules to a size even smaller than those of breast milk. The curd is light, flaky and easily digested. The vitamins remain practically unaltered, and the mineral salts are presented in an assimilable form. That is why babies who are deprived of their natural food thrive so well on Lactogen.

## Whenever a Heart Diagnosis MUST Be Complete

**O**F importance comparable to the diagnosis of cardiac disease is the recognition of its *absence*. Only an electrocardiogram permits definitely ruling out the many serious heart affections that are not discoverable by auscultation.

Not only does ownership of a VICTOR Electrocardiograph give you that essential second opinion in such cases but because the tracings cost so little, you can afford to check routinely in *all* cases where the heart is suspect. The most advanced instrument of its kind, the VICTOR has a masterfully simple, correct design. That is why you can use it to make accurate heart tests easily and quickly. Also, you can make them anywhere because its power supply is self-contained.

Prove these values by your own test. Take just one revealing electrocardiogram. Examine how simply it operates. See how these graphic tests

*assure of continual satisfaction to practitioners, cardiologists and hospitals the world over*

*You can take it with you, to make heart tests on your patients wherever they are*

point the way to surer, earlier diagnosis, as well as to more exact prognosis. Then you can better appreciate the advantages that daily use of this low priced portable instrument would bring to your practice. For a free demonstration or an illustrated booklet describing what the VICTOR Electrocardiograph will do for you, simply post this coupon now. Neither request will obligate you.

- ☐ Please send me the free booklet that describes the new VICTOR Electrocardiograph and what it will do for me.
- ☐ Please arrange with me for a demonstration (no obligation).

# Modern Iron Therapy

Iron Jelloids are an elegant and reliable means of administering the protocarbonate of iron. The preparation has none of the disadvantages of Pil Blaud. The iron content remains fresh and unoxidized indefinitely and

injury to teeth is avoided.

The Jelloids' are highly effective in the treatment of achlorhydric anaemia and indeed in all the simple anaemias in which massive iron therapy is indicated.

## Iron Jelloids

You are cordially invited to apply for samples for clinical test.

### TOXAEMIAS OF PREGNANCY

Because of its general alkalinizing, eliminative and antiseptic action, SALVITAE tends to obviate fermentative and putrefactive changes in the intestinal tract—so important in the treatment of pregnant states. SALVITAE helps to dissipate headaches, vertigo, insomnia, etc., which so often presage an impending uremia.

**SALVITAE**

It serves to prevent or clear up oedema, activates safely the sluggish kidneys and relieves dyspnoea and cardiac embarrassment. SALVITAE given to a woman throughout the gravid state practically insures her against toxæmic or acidotic disaster.

Professional samples and literature gladly sent on request.

### LOCAL TREATMENT OF PSORIASIS ★

Not only does Psoriasis respond readily to local treatment with Sphagnol Peat Ointment, but the relief is lasting. Neither dingy-red nor painful psoriasis is annoying and unsightly. In cases where the correction of faults in clothing and diet brings no satisfactory response, regular applications of Sphagnol Peat Ointment prove beneficial in a very short time. Sphagnol con-

tains the soothing healing distillates of peat. It is a natural antiseptic whose consistent use generally produces lasting relief. In case you have had no personal experience of Sphagnol, we shall be pleased to send you a clinical size sample for testing, if you will write to Peat Products (Sphagnol) Ltd, Dept B M J 4 21 Bush Lane London EC 4.

## The problem of SURGICAL STOCKINGS

Doctors who prescribe Compri-Vena Stockings are sure that the most beneficial support is given as each one is made to the patient's measurements and needs. They have long been recommended for Varicose and in conjunction with Injection Treatment as well as during and after Pregnancy. They are also invaluable in relieving undue leg strain. Compri-Vena Stockings are rubberless and yet elastic, are washable, cool in wear and invisible under ordinary silk stockings. They give real relief and preserve the shape of the legs. A skilled staff carefully follow all doctors' instruction. Full details from

**PRIVATE PRACTICE**—Private practice is not allowed as of right, but in the case of some appointments it is permitted on certain conditions

**QUARTERS**—In Tropical Africa free quarters or an allowance in lieu are provided. In Malaya quarters are provided at an annual rental not exceeding 6% of the officer's salary

**PASSAGES**—Free first class passages are provided on first appointment and when proceeding on and returning from leave. Assistance is also given towards family passages

**TERMS OF APPOINTMENT**—The appointments are pensionable subject to a probationary period which varies from two to three years

**COURSES OF INSTRUCTION IN TROPICAL MEDICINE AND HYGIENE**—Selected candidates will normally be required to attend a course of instruction leading to the Diploma in Tropical Medicine and Hygiene before proceeding overseas

**DUTIES**—Although Medical Officers are appointed in the first instance for general service there are opportunities for work in special branches of medicine and surgery in public health and in medical research

Further particulars and forms of application may be obtained from the Director of Recruitment (Colonial Service), 8, Buckingham Gate, London, S W 1

# ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in July, 1938

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty

At the end of three years' service, officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000

At the end of five years' Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax)

Full opportunities exist for transfer to the permanent list and periods of unemployed or half pay are very rare. The assistance of private income is not necessary for the purpose of supplementing official pay and allowances

Opportunities are available for officers on the permanent list for postgraduate study, to specialise, to take higher examinations and to obtain further qualifications

Naval Medical Officers are included in the Scheme for Marriage Allowance under the same conditions as for other Naval Officers

Copies of the regulations for entry and conditions of Service, including rates of pay, allowances and retired pay may be obtained from the Medical Director-General of the Navy, Admiralty, S W 1, and from the Deans of all Medical Schools

Applications for entry from intending candidates must be received not later than 31st May, 1938

**BOROUGH OF HESTON AND ISLEWORTH****APPOINTMENT OF WOMAN ASSISTANT MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER**

Applications are invited from duly qualified medical women with at least three years experience and also holding a Public Health qualification for the above mentioned post. The successful candidate will work under the supervision of the Medical Officer of Health.

The work will include medical inspection of school children, bacteriological work, Maternity (Antenatal) and Child Welfare work and such other duties as may be allotted. The candidate appointed may also be required to act as Medical Supervisor of Midwives and it is desirable that applicants shall hold qualifications in accordance with the Midwives (Qualifications of Supervisors) Regulation, 1917 particulars of which will be furnished with the application form.

The person appointed will be required to devote her whole time to the duties and will not be allowed to engage in private practice. The salary will be at the rate of £500 per annum rising by annual increments of £25 to £600 per annum.

The post will be a designated post for the purposes of the Local Government and Other Officers Superannuation Act 1922 and the appointment will be subject to the passing of a medical examination in connection with the post.

The appointment will be terminable by one month's notice on either side. The person appointed must live within the Borough of Heston and Isleworth.

Form of application and terms of appointment can be obtained from the Medical Officer of Health, 941 Bush Road Hounslow.

Applications accompanied by copies of not more than three recent testimonials must reach the undersigned not later than noon on Wednesday May 15th 1938.

# CITY OF BIRMINGHAM

## MENTAL HOSPITAL DEPARTMENT

### RUBERY HILL AND HOLLYMOOR DIVISION

The Committee of Visitors invite applications from duly qualified medical men for the position of Junior Male Assistant Medical Officer. The successful candidate will be required to reside in the Hospital.

The commencing salary will be £350 per annum plus the usual residential emoluments of board, lodging, laundry and attendance. An increase of £50 will be granted on completion of twelve months satisfactory service and thereafter in years of £25 per annum up to a maximum salary of £450 per annum. An additional £50 per annum will be paid to a holder of the D.P.M. qualification or to a person obtaining the D.P.M. after appointment. All fees received in connection with the Fund will be required to be paid into the Rubery Hill Fund but to make arrangements for reports on compensation cases and Coroner's inquiries the fees can be retained.

A person who has held for at least six months a medical or surgical residential post in a general hospital will be regarded as having an additional qualification. Previous mental hospital experience is not essential but experience in the administration of anaesthetics is desired.

The candidate appointed will be required to pass a medical examination and will be placed on the permanent staff after one year's satisfactory service, when he will be required to contribute under the A.S.M. Officers' Superannuation Act 1909. He will be required to reside in such institution belonging to the Mental Hospitals Committee as they may from time to time direct. The appointment is subject to one month's notice on either side.

Applications, stating full particulars of qualifications, experience and age, must be accompanied by copies of the recent test certificates and be addressed to the undersigned as to be received not later than May 11th 1938.

May 4, 1938

By Order of the Council

G. C. ANDERSON Secretary

### HULL ROYAL INFIRMARY

Applications are invited for the post of **SECOND CASUALTY OFFICER (male)** vacant now. Salary £150 per annum plus board residence and laundry.

In addition to carrying out duties in the Casualty Department the officer appointed will act as House Surgeon to one of the Honorary Assistant Surgeons and will thus obtain Ward and Theatre experience. He will be eligible for promotion to a more senior post when a vacancy occurs.

The appointment will be for a period of six months but will be determinable at any time by one month notice on either side.

Applications, giving particulars of age, experience and nationality to either with copies of testimonials should be addressed to the undersigned.

R. J. CARLESS  
April 20th 1938 House Governor

### ANCHASTER HOSPITAL, MANCHESTER

#### ORTHOPAEDIC REGISTRAR

Applications are invited from duly qualified Medical Practitioners. Duties to assist the Hon. Orthopaedic Surgeon in the Out Patient Clinic on Tuesday afternoons at 2 and on Thursday mornings at 9. Honorarium £200 per annum. Appointment for 12 months terminable on January 1st of each year.

Applicants stating age, qualifications, experience and full particulars to be forwarded on or before May 11th, to either with copies of three recent testimonials.

By Order of the Board  
HERBERT J. DAFFORNE,  
Gen. Supt. and Secy.

### STIRLING DISTRICT MENTAL HOSPITAL

#### Larbert

**JUNIOR ASSISTANT MEDICAL OFFICER** required. Commence salary £200 per annum rising by annual increments of £25 to £300 with board and laundry. Appointment subject to provisions of Asylum Officers' Superannuation Act.

Apply stating age and experience with testimonials to the Medical Superintendent.

### SOUTH MIDDLESEX AND RICHMOND JOINT HOSPITAL BOARD

#### SOUTH MIDDLESEX FEVER HOSPITAL ASSISTANT RESIDENT MEDICAL OFFICER

Applications are invited from fully qualified Medical Practitioners for the above position. Duties to commence as soon as possible. The appointment is for a period of one year at a salary of £200 per annum with board and lodging. Preference will be given to candidates who have held a recent appointment in a General Hospital. Experience in anaesthetics desirable.

Forms of application with full particulars of duties may be obtained from the Medical Superintendent, South Middlesex Fever Hospital, Mortimer Lane, North Middlesbrough. Applications on pre-printed forms should be returned to him on or before Monday, May 16th 1938.

S. C. T. LITTLEWOOD  
14 Church Street Clerk to the Board  
Kings-on-on-Thames  
April 20th 1938

## REDUCED TOXICITY

In anti-bacterial therapy is an important consideration. Abundant clinical evidence has established RUBIAZOL as a highly active and safe remedy for all haemolytic streptococcal infections.

### ADVANTAGES INCLUDE

- The most acute cases respond to a daily dose of 2 grammes (30 grains)
- No clinical manifestations of toxicity noted after two years trial on the Continent
- Is effective in prophylaxis and treatment

## TRADITIONAL LONDON

THE SAVOY PALACE  
about 1640

*Built in 1245 it was given by Henry III to Peter Count of Savoy Uncle of his Queen and later conferred upon her son Edmund Earl of Lancaster. Only the Chapel Royal remains to day and is still supported from the revenues of the Duchy of Lancaster.*

London Hospital Catgut has no less fine traditions behind its development to a leading place in the esteem of Surgeons the world over. It is a product of scientific research, made throughout at the London Hospital under licence of the Ministry of Health.

## for Systemic Alkalization

A palatable, granular, effervescent salt for the treatment of acidosis

A combination of sodium, potassium, calcium and magnesium, in the form of carbonates, phosphates and citrates — no tartrates, sulphates or lactates, and no sodium chloride

For acidosis in fevers, influenza, nephritis, cardiac disease, pregnancy, diabetes, cyclical vomiting, acidosis associated with anaesthesia, tetany, rheumatic conditions

One heaped teaspoonful, three or four times daily in a glass of water, is an efficient, refreshing neutralizer of excessive local or systemic acidity. After effervescence has subsided milk or fruit juices may be added, if preferred

A liberal supply for clinical trial sent on request

## NOTABLE NUMBERS

THE JEWS HOUSE, No 1 STEEP HILL, LINCOLN—This ancient house, which dates back to Norman times, was built about 1100, and is said to be one of the oldest inhabited houses in England

The slow maturing process of time plays its part in the production of that other notable number—Player's No 3. Mellowness, distinction of aroma, flavour, and finer quality in the tobacco—these are the reasons why No 3 is such a notable smoke.

PLAYERS  
No 3 are  
supplied  
either plain or cork-  
tipped so ask for which  
you prefer

## Herman's Practice of Urology

**Just Ready**—An up to date presentation of the medical and surgical aspects of urology. There is special emphasis on practical essentials as they relate to diagnosis and treatment. By LEO HERMAN, I.S. M.D. Professor of Urology, University of Pennsylvania Graduate School of Medicine. Octavo of 225 pages. 24 illustrations. Cloth 4/- net.

## Wolf's Endocrinology

**A Great Success**—Covers the entire field of endocrinology in modern practice. Gives symptoms, methods of diagnosis, examination, in taking laboratory tests, management and treatment.

Octavo of 1018 pages. Illustrated by WILLIAM WOLF, M.D. M.S. I.H.D. Cloth 42/- net.

## Griffith and Mitchell's Pediatrics

**Second Edition**—A one-volume pediatrics that tells how to examine how to diagnose what treatments to institute. Particularly full on infant feeding.

Octavo of 1104 pages with 293 illustrations including 15 plates in colour. By J. P. CROKER GRIFFITH, M.D. Ph.D. Emeritus Professor of Pediatrics, University of Pennsylvania, and A. CARMEL MITCHELL, M.D. B.K. Rochester Professor of Pediatrics, College of Medicine, University of Cincinnati. Cloth 42/- net.

## Levine's Clinical Heart Disease

**Fourth Large Printing**—A clinical discussion of the many frequent heart disorders including cores of the author's own prescriptions. There are 444 electrocardiograms on 95 figures.

Octavo of 470 pages. Illustrated by SAMUEL A. LEVINE, M.D. F.A.C.P. Assistant Professor of Medicine, Harvard. Cloth 24/- net.

## Tuft's Clinical Allergy

**A New Book**—Today's knowledge of allergy and its clinical application in diagnosis and treatment.

By LOUIS TUFT, M.D. Chief of Clinic of Allergy and Applied Immunology, Temple University Hospital. Octavo of 711 pages. Illustrated. Cloth 36/- net.

## Merritt and Fremont-Smith on Cerebrospinal Fluid

**Entirely New**—Based on 21,000 fluids examined. Applies the findings to clinical diagnosis.

By MERRITT, M.D. Assistant Professor of Neurology, and F. M. SMITH, M.D. formerly Assistant Professor of Medicine, University of Pennsylvania. With Foreword by JAMES B. AYER, M.D. Octavo of 353 pages. Illustrated. Cloth 22/- net.

## Padgett's Surgical Diseases of Mouth and Jaws

**New!**—A brand new book devoted to medical as well as surgical treatment. Includes a chapter on irradiation. By EARL CALVIN PADGETT, B.S. M.D. F.A.C.S. Associate Professor of Clinical Surgery, University of Kansas. Octavo of 250 pages. 334 illustrations. Cloth 4/- net.

## Gifford's Ophthalmology

**Entirely New**—A concise discussion of the medical and modern ophthalmology. Includes Eye Surgery, General Diseases and a wealth of information on vision and colour illustrations.

By STANFORD R. GIFFORD, M.A. M.D. F.A.C.S. Professor of Ophthalmology, University of California. Illustrated in colour. Cloth 12/- net.

## Warbasse Smyth's Surgical Treatment

**Both Medical and Surgical**—This new book gives the reader a complete and concise treatment of the most important surgical diseases.

The latest information on all the latest surgical procedures with 100 illustrations. By WARBASSE SMYTH, M.D. F.A.C.S. Surgeon, University of California Medical School. Illustrated in colour. Cloth 12/- net.

## Beckman's Treatment

**Just Ready—New (Third) Edition**—This book including hundreds of illustrations and diagrams, gives the reader a complete and concise treatment of the most important surgical diseases. By P. P. BECKMAN, M.D. Professor of Surgery, University of California. Cloth 12/- net.

## Cecil's Medicine

**New (Fourth) Edition**—Here is medicine as practiced by 140 leading authorities. It is modern practice in every way. Completely revised for this revision.

Octavo of 1140 pages. Illustrated. Edited by F. C. CECIL, M.D. Professor of Clinical Medicine, Harvard. Cloth 42/- net.

## Curtis' Obstetrics and Gynecology

**Three Volumes**—A complete work on the medical and surgical covering the entire literature of Women's Diseases. A veritable atlas. 210 illustrations.

The octavo of 2100 pages. 300 illustrations. By CURTIS, M.D. Professor of Obstetrics and Gynecology, University of California. Illustrated in colour. Cloth 42/- net.

## Mason's Pre-operative and Post-operative Treatment

**Thoroughly Up to Date**—Presents a complete and concise treatment of general and special cases of pre-operative and post-operative treatment.

Octavo of 210 pages. Illustrated. By MASON, M.D. F.A.C.S. Assistant Professor of Surgery, University of California. Cloth 12/- net.

## Christopher's Minor Surgery

**Third Edition**—The standard text for the medical student and the general practitioner.

Octavo of 110 pages. Illustrated. By CHRISTOPHER, M.D. F.A.C.S. Professor of Surgery, University of California. Cloth 12/- net.

# FOOT COMFORT

## By wearing 'APTERNA' HEEL-LESS SHOES

These shoes are designed in the common-sense knowledge that the majority of foot troubles are due in large measure to faulty footwear which aggravates the trouble and does not permit the natural exercise and freedom which is essential to foot health

*Charles H. Baber*

LANGHAM HOUSE, UPPER REGENT ST, W 1

Any of the common foot ailments mentioned in the above diagram can be successfully prevented and relieved by prescribing the correct series of "Apterna" Heel-less Shoes

★ Write for free 'Apterna' Booklet and Catalogue

'Apterna' Shoes are available for men and women and children

# A mobile office

roomy easy to get in and out of airy and well lit quick to start under all conditions and fast And withal a very distinguished motor car

## ANSWERS EVERY NEED of the DOCTOR

**EASY STARTING**—In the Wolseley 14/56 h.p. a thermodynamically controlled water system does away with warming up delays and sluggish pulling. A 12 volt electric system and twin batteries ensure ample starting energy.

**ROOMINESS**—Quick and easy exit through wide doors fresh air renewal every 60 secs and anatomically correct seating mean lack of fatigue on even the longest day.

**NIGHTWORK**—Powerful headlamps twin fog lamps stop and reversing lamps and

duplex screen wipers less than the rain of day and rainy nights.

**ECONOMY**—24 to 28 m.p.g. per gallon is good for a 14 Wolseley's stabilized production policy lowers depreciation.

**QUIET**—Body, door and floor are completely insulated from noise—no interference from fumes.

**APPEARANCE**—The Wolseley 14/56 either as a Saloon or in its Salon de Ville form is a distinguished handsome car—very indicative of the standing of its owner.

# WOLSELEY

## 14/56—"the doctor's car"

The price of the 14 h.p. Saloon is from £60—the Salon de Ville £70—18/50 h.p. a/c from £50 Super Sixes from £30 and the 14/55 h.p. from £40. Dunlop Tyres, Traction Safety Glass and Jacks.

# Most easily concealed efficient Hearing Aid

**T**HE New V.P. Maxade for deaf persons is a marvel of compact scientific construction, comprising three units (each about the size of a cigarette case), easily concealed in the clothing or carried in the handbag. A 3-valve amplifier with highly sensitive crystal microphone is employed and can be used for bone or air conduction. Professional and business people whose livelihood depends on good hearing will welcome this unobtrusive and reliable instrument.

Maxade is entered upon the Approved List of the National Institute for the Deaf and consistently used and prescribed by the principal hospitals and clinics.

*The New V.P.*

## MAXADE

A Model will gladly be sent for free clinical test. Details of the V.P. Model and other reasonably priced Maxade Models from Mr. W. Scott Worthington, F.R.S.A.

**PETO SCOTT CO. LTD., 77, CITY ROAD, E.C.1**  
(ACOUSTIC ENGINEERS SINCE 1919)

*Is a sufferer from deafness for 20 years it may be said  
one who has tried practically every instrument of the  
I find that the V.P. Maxade is distinctly the best  
I can find and is the essence of convenience.*  
T.C.N. (Littlehampton)

*I find it a very efficient instrument and in my opinion it is  
equal to other hearing aids at approximately double the  
price. I shall have pleasure in recommending it.*  
—M.L. (London N.13)

*Re Maxade. I have pleasure in informing you that I  
find it puts at the test of the instrument I have tried up to  
the present. —M.R.C.S. (Lond.) F.R.C.P. (Lond.)*

# FOOTWEAR & *National Fitness*

**M**EDICAL men have, of course long realised the importance to fitness of properly made and accurately fitted footwear

It has been said that manufacturers and shoe retailers have failed in the past to provide such footwear, and that retailers have lacked the necessary knowledge and skill to fit shoes correctly

We would draw attention to the fact that we have long been alive to the importance of this matter, and have concentrated for many years upon the production of shoes the correct construction of which meets with the approval of medical men, and which can be fitted with great accuracy by properly trained assistants

There are more than 300 retailers who are fully trained and qualified to fit our shoes correctly

Church's Arch Moulded shoes are made in a wide variety of styles for men and women (there is nothing of the surgical shoe about them). They contain fixed supports for the longitudinal and metatarsal arches and they are available in a full range of graded fittings, which include six different widths in sizes and half-sizes—upwards of 100 fittings in all

We will gladly send particulars to anyone interested

## MERSALYL B.D.H.

The use of mercurial diuretics has become an established routine in ordinary clinical practice. The superiority of the sodium salt of salicyl-( $\gamma$ -hydroxymercuric- $\beta$ -methoxypropyl) amide-O-acetic acid over other diuretics is officially recognised, and it has been included in the B.P. Addendum under the name Mersalyum and as Injectio Mersalyli.

Mersalyli is indicated in various oedematous conditions, particularly

those associated with cardiac dysfunction.

It will be found in most cases that premedication with digitalis considerably enhances the effect of Mersalyli B.D.H.

Mersalyli is available in a sterile buffered solution of Mersalyli B.D.H. in ampoules of 1 c.c. and 2 c.c., and in suppositories for adjuvant treatment or for administration (following a single injection) in mild cases.

# VERONIGEN

A liquid preparation of the Hypnotic Barbitone or Diethylbarbituric acid has long been desired as a useful means of procuring sleep. When given in reasonable doses it is claimed that it does not produce any toxic symptoms whatever nor is cumulative in action and in ordinary cases of insomnia one fluid drachm of VERONIGEN is sufficient dose for an adult. As a preventive of post operative vomiting one to two fluid drachms of VERONIGEN may be given one and a half to two hours before general anaesthesia is produced and as a result much less of the anaesthetic is required. As BARBITONE has a slight diuretic act on the mixture can be used more safely than other hypnotics when the heart is weak. Where sleeplessness is a concomitant of pain rest and relief can frequently be obtained by the administration of one drachm of VERONIGEN and two drachms of ELINIR ACID ACETO SALICYLIC (Hewlett's).

**DOSE FOR ADULTS**—One fluid drachm diluted one hour before going to bed  
**For Nervous Sleeplessness in Children**—10 to 20 minims diluted

*Introduced and Prepared only by*

# 'AMYTAL'

BRAND

*Iso-amyl Ethyl Barbituric Acid*

## FOR SEDATION AND HYPNOSIS

● The tranquil sleep of children is always the envy of less fortunate adults to whom at times this boon is denied because of sickness or other conditions which upset the psychic or emotional equilibrium

'Amytal' supplies the relaxation and sleep which are essential to recuperation of vital forces. It may be prescribed wherever there is need to combat insomnia, restlessness, or apprehension. A noteworthy margin of safety is characteristic of 'Amytal' and since destruction of the hypnotic within the body appears to be accomplished rapidly there is little tendency to unwelcome side reactions or after depression.

'Amytal' is supplied in  $\frac{1}{4}$  gram,  $\frac{1}{2}$  gram, and 1 $\frac{1}{2}$  grain tablets in bottles of 10 and 500.

# "ALOCOL"

*Colloidal Hydroxide of Aluminium*

## Rational Antacid Therapy

**A**PART from those cases due to actual organic disease, the treatment of the syndrome of symptoms known as indigestion, generally resolves itself into an attempt to overcome hypersecretion of acid and to soothe the irritated or inflamed gastric mucosa.

That Alocol possesses intrinsic qualities which render it particularly valuable as a gastric sedative and antacid is now well established. Its freedom from the constipating effect of bismuth, the laxative action of magnesium salts and the gas-forming properties of sodium bicarbonate are especially noteworthy.

Alocol forms with the gastric contents a colloidal jelly which has the power of adsorbing free hydrochloric acid. Its markedly soothing effect on the gastric mucosa promptly relieves pain and discomfort. It does not interfere with the normal process of digestion and is free from the danger of alkalosis.

*Complete chemical history of Alocol with convincing clinical reports and supply for trial sent free to physicians on request*

## RADIOSTOLEUM

(Standardised Vitamins A and D)

The ill-effects which arise from the all-prevailing shortage in the normal dietary of Vitamins A and D are counteracted by the administration of Radiostoleum, a highly active preparation which contains these two vitamins in accurately-standardised and properly-balanced proportions. The daily ingestion of two or three capsules of Radiostoleum, or their equivalent in the form of Radiostoleum liquid, aids in the preservation of epithelial integrity, thus preventing the inroads of infective organisms, particularly through the nasal cavities, the throat and respiratory tract.

## FITNESS

### AND THE FAT-SOLUBLE VITAMINS

Whether for expectant and nursing mothers, growing children or rapidly developing adolescents, Adevolin provides essential protective elements at all seasons.

Special demands for Adevolin during the summer may be due to a deficiency of fat-soluble vitamins in the diet as the consumption of fats is greatly reduced in hot weather. Moreover, a seasonal tendency to metabolic and gastro-intestinal disturbances may result in a limitation of vitamin intake and assimilation. For these reasons doctors use Adevolin to ensure

a sufficiency of vitamins A and D. Vitamin A enhances resistance to infection of the respiratory, intestinal and genito-urinary systems; vitamin D governs calcium metabolism and safeguards the integrity of skeletal and dental structures. Together in Adevolin these vitamins promote the orderly development and maintenance of the tissues. The effect of well-being conferred by Adevolin regularly demonstrates the high "tonic" qualities of this rational combination and concentration of vitamins A and D.

## FOR EFFECTIVE CONTROL OF PAIN

AMONG the many and diverse analgesics which have been evolved by modern chemical research, acetyl salicylic acid retains its reputation as one of the safest and most effective. Its tendency to liberate salicylic acid—the irritant properties of which are well known to physicians—has however caused many to hesitate to employ it as widely as it deserves. Exhaustive trial in hospital and private practice proves that "Alasil" definitely solves the problem of administering acetyl-salicylic acid in an effective form being free from the risk of irritating the stomach or bowels or of causing general reactions.

*A supply for clinical trial with full descriptive literature sent free on request*

In "Alasil" the desirable therapeutic effects of acetyl salicylic acid are well exhibited by its calcium acetyl salicylate moiety while the presence of "Alcol" (Colloidal Hydroxide of Aluminium) a powerful gastric sedative and antacid obviates any tendency to gastric irritation. The superior absorbability of "Alasil" over ordinary salicylate compounds and its freedom from the risk of liberating free salicylic acid in the stomach have been well proved by careful experimentation. "Alasil" can be prescribed with perfect safety to patients of all ages and in larger doses than ordinary salicylate compounds.

ANALYSTS IN CHEMISTRY AND PHARMACY  
ARMOUR HOUSE ST MARTIN'S LE GRAND LONDON E.C.1

Your patient . . .

Labour is difficult and prolonged. During the hours of strain and afterwards—you will want to do all in your power to maintain this young mother's strength.

Brand's Essence is a practical and efficient stimulant at this and all times when the minimum energy can be spared for digestive effort. The ease and speed with which Brand's is assimilated are due to a complete absence of solids and irritants. Protein-sparing action takes place to a marked degree. The essence does not cause thirst and can be given at a moment's notice with a teaspoon.

# ANAHÆMIN B.D.H.

*In the treatment of Pernicious Anæmia*

The specificity of Anahæmin in true pernicious anæmia is firmly established, and clinical evidence substantiating this continues to accumulate

It is usually found that an initial injection of 2 cc followed by 1 cc every 10 days constitutes effective treatment, maintenance treatment consisting of 2 cc monthly

Furthermore, in those cases which are

complicated by a dietary deficiency or by some form of secondary anæmia, similar beneficial results follow if iron in a readily assimilable form (for example, as Syrup of Citrated Ferrous Chloride B D H) and Ascorbic Acid B D H are administered collaterally with Anahæmin B D H

*Samples of any of the above-mentioned products will be sent on request*

# Diabetes

Chemical experience has now definitely established that diabetes can be traced to an intricate biochemical disturbance of metabolism, which extends far beyond the limits of the carbohydrates. From this it follows that the state of the nervous system plays a most important part—nervous complications of the disease are common and the harmonious balance of endocrine action, which is necessary for a normal carbohydrate metabolism, is, of course, controlled by the nervous system.

Sanatogen's tonic effect upon the nerves has, as many clinical records show, conferred definite benefit in the treatment of diabetes. This highly concentrated food contains 95 per cent pure milk casein *chemically combined* with 5 per cent sodium glycerophosphate. It is very easily digested. Literature giving detailed reports on its effect in diabetes will be forwarded, free of charge, on request.

"I have now completed my test of Sanatogen on diabetic patients. A man of 28, who has had Diabetes for 12 years has been sugar-free for 8 weeks, in spite of the fact that I have gently lowered his Insulin weekly for that period. A man of 55 is practically sugar-free for 8 weeks, although as above. A woman of 48 has reduced her sugar from 2 and 3 per cent to 5 per cent during the time she has been taking Sanatogen. In my own case, I have been able to reduce my daily Insulin by 20 units, and I now average from 5 per cent to 1 per cent sugar. I have pleasure in testifying to the efficacy of Sanatogen for Diabetes."—M R C S, L R C P

## a BÖNOCHORD POCKET VALVE DEAF AID

BÖNOCHORD High Fidelity Amplifiers are preferred by all who demand the best obtainable in hearing aids

Here is a new model which can be worn on the person while in no way sacrificing the high quality of reproduction for which BÖNOCHORD Amplifiers are recommended by medical men

Frequency response is from 200 to 8000 cycles per second. A Piezo electric microphone and three stages of amplification are employed also automatic volume control and noise-suppression. The aid is entirely dry battery operated with flash lamp cells for low tension which are obtainable everywhere

All models are available for home trial. Any BÖNOCHORD instrument will be sent for clinical test free of charge on request. Send for the BÖNOCHORD booklet *The Hearing Aid Par Excellence* giving full details illustrations and prices of all models

## CLINICAL PROBLEMS OF THYROTOXICOSIS

By

PETER McEWAN, M.A., M.B., F.R.C.S. Ed

Honorary Surgeon Bradford Royal Infirmary

(WITH SPECIAL PLATE)

Among the many interesting problems of thyrotoxicosis there is none more urgent and more obscure than the high and rapidly increasing death rate. During the year 1936 no fewer than 1,696 deaths were attributed to that condition in England and Wales. There has been a steady rise for many years the exact figures being

Year	1913	1914	1915	1916	1917	1918	1919	1920	1921	1922	1923	1924	1925
Males	360	338	322	470	490	466	473	464	433	490	69	54	6
Females	360	434	400	399	395	357	473	464	433	490	69	54	6
Year	1925	1926	1927	1928	1929	1930	1931	1932	1933	1934	1935	1936	1937
Males	64	84	91	119	123	111	135	165	181	137	137	143	143
Females	630	743	852	933	936	1114	1166	1259	1444	1315	1373	1433	1433

It is a curious fact that during the last ten years the operation for the cure of thyrotoxicosis has attained its peak of excellence and has been pronounced the safest operation in major surgery. No agreement has been reached as to how to explain this wide gap between the magnificent possibilities of major surgery on the one hand and the rapidly rising mortality on the other. The main purpose here is to examine and discuss this problem. The primary method of approach has been by an investigation of the deaths during 1936. Through the courtesy of the Registrar-General I was furnished with the particulars of each death in England and Wales during that year as regards sex, age, place of residence, place of death, and causes of death. A careful analysis of these returns has been made from various points of view. For convenience the tables will be given first. They will be used in the subsequent discussion and interpreted in the light of clinical experience and I ask for indulgence if I fail to avoid some of the many fallacies inherent in statistics and deductions therefrom.

TABLE I—Geographical Distribution

County	Number of Deaths		Gr. Annual Population	Percentage of Deaths
	Annual Average for Years 1913-19	Year 1936

## Geographical Distribution

A glance at the map (Fig A) or a study of the figures given above will show the unevenness of the distribution, the highest percentage death rate occurring in Westmorland, the mountainous counties of Wales, and Huntingdon. A similar map was published by Campbell (1924-5) showing the geographical distribution of the death rate during the group of years 1913-19. The close parallelism of Campbell's map (Fig B) and my own is remarkable. These two maps bring up two points of practical interest regarding thyrotoxicosis. First, the stress and strain of modern life has by some been regarded as an important factor in causation. Campbell's map does not bear this out, outlying mountainous counties not being the areas of greatest stress. Now if during the twenty years that intervene between the maps (the mortality rising from an average of 442 to 1,696) the stress of life were an important factor the distribution must have altered in favour of the big cities. It has not changed, therefore the stress and strain of life is, if a factor at all, a minor one, whereas the geographical factor is a major one, in causation. The second point is, Does the death incidence correspond to the incidence of simple goitre? Campbell studied this question carefully. He found that it was impossible to obtain reliable data as to the distribution of simple goitre, but he concluded that the evidence pointed to some degree of correspondence between the incidence of simple goitre and that of the thyrotoxic deaths. If this be true, and we take into account the acknowledged fact that many simple goitres become toxic, the further question arises, How far may the death rate be reduced by timely operation upon simple goitres or goitres that are in the early stages of toxicity?

### Sex and Age Incidence

The proportion of deaths as regards sex has scarcely altered: one man dies to seven or eight women: this fact scarcely supports the strain of life as a notable causal factor. Between the ages of 10 and 30 years 118 deaths occurred—sixty five medical fifty three after operation: the number of surgical deaths at these ages appears unduly high. Many thyrotoxic patients live to a good old age (60 to 90 years). Have these old people become toxic shortly before death or have they suffered for many years from ill health and debility? Could operation have given them a longer and healthier life?

others not recorded) are numerous and the deaths under anaesthesia (twenty one) frequent. The varied nature of the anaesthetics used in these fatal cases suggests that skill in administration rather than the anaesthetics employed is the important factor in safety.

### The Medical Death Rate and Complications

The mention of cardiac mischief in 908 cases and of auricular fibrillation in 298 of these shows how conspicuous a place cardiac complications take in the thyrotoxic picture. The vascular complications (embolism, thrombosis, hemiplegia) come next in frequency. It is noteworthy how often the brain is affected (sixteen

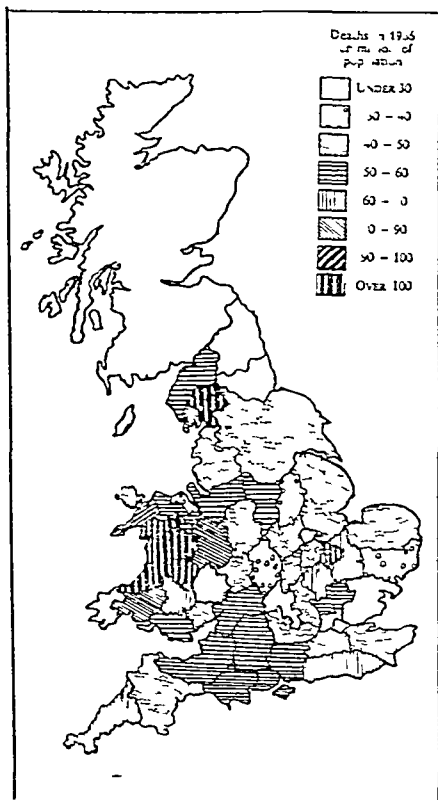

FIG A.

FIG A—Map of England and Wales showing the distribution of deaths from thyrotoxicosis during 1941 according to the Registrar General's Reports (based on place of residence, not place of death).

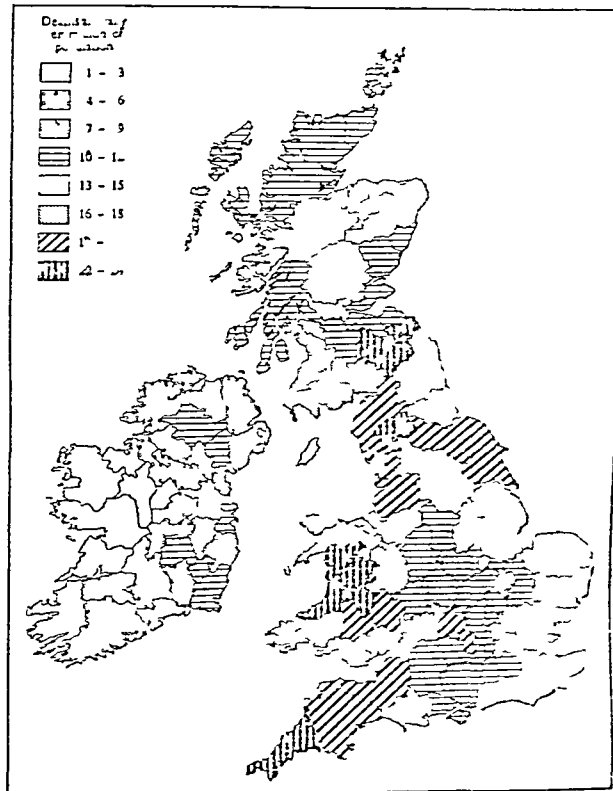

FIG B

FIG B—Map of Great Britain and Ireland showing the distribution of deaths from exophthalmic goitre during 1911-19 according to the Registrar General's Reports (Campbell).

### The Surgical Deaths

Operation is stated to be the cause of death in 276 cases. The number of deaths following operation may exceed this figure as operation may not have been mentioned in certain cases especially in the 219 cases in which thyrotoxicosis alone (or a synonym) is given as the cause of death. Indeed de Courcy Wheeler (1934) states that in those severe cases where ligation of arteries is performed if the patient dies surgery is blameless: the operation therefore has no title to appear on the death certificate. The certifier may consider that death has occurred in spite of and not because of the operation. The figure of 276 appears high: the fatal chest complications (twenty seven specified and doubtless many

cases) and that auricular fibrillation occurs frequently, whereas arteriosclerosis and hyperostosis are mentioned only five times suggesting that auricular fibrillation is a more notable factor in the production of thrombosis and embolism than high blood pressure. Nephritis is mentioned twenty three times, pneumonia twenty times, the tonsils no more than once, rheumatism and also in the production of a connecting link. Diabetes and glandular disease often (twelve times) than other vascular diseases especially pulmonary tuberculosis and abdominal disease are dangerous to the thyrotoxic patient so also no doubt the operation on these organs. Tuberculosis is not mentioned in the same way as the other diseases mentioned once or twice and once as a cause of death.

kyphosis this is in line with the antagonism that is believed to exist between tuberculous disease and thyrotoxicosis

### The Sphere of Iodine in Thyrotoxicosis

The view is seriously advanced by Joll (1932) that the employment of iodine as a medical treatment is *the* new factor causing the increase in the death rate. It is well recognized that the use of iodine in areas where goitre is endemic may lead to a definite increase in thyrotoxicosis, the increase in the deaths in the hilly districts, presumably endemic goitre areas, would support Joll's view. Many writers emphasize the danger of giving iodine to thyrotoxic patients, and uphold Joll in his contention that iodine should be entirely reserved for the use of the surgeon as a pre-operative safeguard. Fraser (1936), on the contrary, advocates that iodine be given a trial in all cases of thyrotoxicosis. Yet Fraser adds "Iodine does not cure the condition, and it is doubtful if it cuts short the course of the disease." There is, however, no doubt at all that the case in which iodine has failed, sent later for operation, often causes the surgeon much anxiety, leading to increased hazard and delay. For, as Morley (1936) puts it, iodine acts best on virgin soil. Given for the first time it is a magnificent safeguard against post-operative toxic crises. Its full efficacy is seldom reached during a second or subsequent course. Whereas in acute primary thyrotoxicosis the pulse may often be controlled and kept at 80 during the first administration of iodine, the pulse in the same patient at a later date may race along at 130 to 140 despite the use of that substance, the originally soft and responsive gland being now large, firm, and indifferent. Iodine is to the thyrotoxic patient what opium is to the "acute abdomen"—it masks the symptoms without curing the disease. Doubtless cases recover under iodine and under opium, but for the many failures the penalty is severe. Even in the very acute thyrotoxic crises where iodine must be used as an emergency measure to save life the surgeon should be called in, as these cases may speedily become operable, and the opportune time, if not taken advantage of, may not quickly recur. Unless surgical treatment is permanently excluded in an individual case iodine is best reserved for the use of the surgeon before operation. If iodine as a mode of treatment in general practice were given up it is quite possible that a fall would occur in the death rate.

The dose usually recommended for pre-operative treatment is from 5 to 15 minims of Lugol's solution three times a day for five to fourteen days before operation. The following two cases are of interest as showing that in rare cases this dose may be greatly exceeded with usefulness and safety.

#### CASE I

Mrs. B., aged 28 (acute primary thyrotoxicosis, operated on during a severe crisis)—The patient had enjoyed good health until she suffered from crippling rheumatic arthritis (1929-30). This was cured by six to twelve months' treatment with thymoglandin. The total dose of thyroid extract was trifling. Her health was fair till January 1932 when her doctor pronounced her a nervous wreck. In September 1932, a diagnosis of thyrotoxicosis was made. In March, 1933 she had a severe crisis. This was controlled with iodine, and as authoritative opinion regards operation during a crisis as contraindicated she was sent home till it should pass over. Three weeks later she was returned to the nursing home as an acute emergency case with a running pulse of 180, diarrhoea and vomiting, and in a state of uncontrollable

agitation. Her weight had fallen from a normal of 11 st 10 lb to under 7 st. The patient's restlessness was controlled by general anaesthesia (ether), heroin was administered hypodermically and Lugol's solution per rectum. In twenty-four hours she received 90 minims of the solution by mouth and rectum. Her pulse fell to 80 to 90 per minute. The Lugol's solution was discontinued and heroin was given daily. After five days the effect of the iodine ceased and she relapsed. She was then prepared with Lugol's solution for ten days and on May 15, 1933 the right side and isthmus were operated on, the left side being done on June 5. Convalescence after both operations was rapid and by October, 1933, she had regained normal weight, health, and vigour, and has since remained well.

#### CASE II

Miss H. B., aged 22 was admitted on November 2, 1937, for typical acute primary thyrotoxicosis of a year's duration, with tiredness, nervousness, shortness of breath, palpitation, and sweating but no loss of weight, the pulse rate was often 160 per minute. She had had x-ray treatment from May to September and Lugol's iodine for the same period without benefit. The basal metabolic rate on November 5 was +73 per cent and the blood pressure 168/70. The thyroid gland was symmetrically enlarged and of the firm iodinated type. The patient was kept under medical treatment and the gland became softer and the pulse less rapid but the latter rose very readily to 140 to 150. Lugol's solution was begun on December 28, 7 minims thrice daily. On January 8, 1938, her pulse was still very excitable, and rose to 142 during the period of the doctor's visits. At 2 p.m. on January 8 she had a rectal saline containing 50 minims of Lugol's solution, a half-hourly chart showed a gradual and remarkable descent

dramatic effect of a Lugol saline in an iodized patient (4) the dosage of hyoscine and morphine that can be given in an acute case

### Delayed Diagnosis as a Cause of Death

The surgery of thyrotoxicosis is passing through a stage comparable to that of the long neglected hernia the big fibroid and the late acute abdomen. The same pathetic fear of surgery which delayed treatment of these lesions twenty five years ago is preventing early and safer treatment of thyrotoxicosis to day. The same waiting for a fully developed picture is retarding early diagnosis. An incomplete picture is said to wear a mask. These masks in particular the fibrillating heart in proportion as the distinctive features of the disease become better known are changed from masks to identification badges which suggest the diagnosis and lead to further investigation. Many a thyroid patient having recovered from operation says: "I feel in better health than I have enjoyed for many years—sometimes ten or twenty years—but the diagnosis is recent, and these poor patients have suffered years of ill health." Thyrotoxicosis presents a remarkable variety of clinical pictures. Its symptoms are manifested by disorder of the autonomic nervous system and fall apparently haphazard, with varied emphasis on the organs under autonomic control. Taking the commoner signs and symptoms from the top of the head to the sole of the foot the percentage incidence in cases coming under my care in this part of Yorkshire is roughly: nervousness or mental upset 100 per cent, increased rapidity of the pulse or auricular fibrillation 100 per cent, tremor distinguishable from normal, 90 per cent, easily produced fatigue 80 per cent, loss of weight 80 per cent, palpitation or thumping (or both) 75 per cent, excessive perspiration or dislike of heat 70 per cent, shortness of breath 60 per cent, digestive symptoms 50 per cent, headache 30 per cent, interference with the voice 20 per cent. Eye stare is common, exophthalmos is not so frequent and swelling of the eyelids swelling of the feet anaemia and anginal pain occur now and then. Where these symptoms are too few to render the condition obvious the disease is said to be masked. These masks are limited in number let me mention the chief ones.

### The Thyrotoxic "Masks"

1 *The Cardiac Mask*—This is the commonest a fact clearly brought out in the above statistics. These patients usually come with shortness of breath, some have a brief history others date slight symptoms many years back. Hay (1936), in a charming paper on the thyrotoxic heart, pleads for the earlier diagnosis of those cases and for treatment at a period corresponding to that of the grumbling appendix. If anyone doubts the genuine difficulty which often exists in detecting thyrotoxicosis in those cardiac cases a single reading of Hay's paper will fully convince him and diagnosis is very important as operative treatment is brilliantly successful.

2 *The Mental Mask*—The mental cases come as melancholia mental depression with suicidal tendencies and nervous breakdown with mental symptoms. Dunhill (1937) emphasizes the need for a mental expert to establish the diagnosis.

3 *The Abdominal Mask*—The presenting symptoms may consist of a very accurate simulation of gastric or duodenal ulcer or of a long history of bilious attacks. The following case demonstrates the cure of abdominal symptoms by operation on a goitre.

### CASE III

Mrs. C., aged 48 had had severe stomach trouble for five years (since 1931). The attacks lasted one to six weeks and consisted of continuous epigastric pain relieved (only for a short time) by food. Intervals of freedom lasted two or three months. She had to lie up very often and in 1935 was admitted (after x-ray examination) to have an operation for duodenal ulcer. She was sent to me in February 1936 for the above symptoms and for a right sided adenoma of the thyroid. The adenoma was growing causing dyspnoea on exertion marked fatigue especially during the last two years, sweating tremor and slight tachycardia. The removal of the adenoma (March 5 1936) completely cured the dyspnoea. The patient writes as follows: "It is no event for me since my operation my neck is now normal the adenoma unnoticeable and my dyspepsia trouble a thing of the past. I take ordinary food sleep well and my weight is normal. In fact I feel I have taken a new lease of life."

4 *General Debility and Nervous Breakdown*—Cases which have lurked behind this diagnosis to many years enter on a new era of health when the disease is identified and treated.

5 *The Absence of a Clinically Detectable Goitre*—Careful examination will often find a goitre which is not at first obvious. Joll speaking from his very large experience declares that the thyroid is invariably enlarged in thyrotoxicosis. I believe personally that there are exceptions to this rule as for example the following case.

### CASE IV

Mrs. H. aged 49 had had typical symptoms of the toxicosis of an aggravated type. The basal metabolic rate was fully and satisfactorily taken was +4 per cent. There was no goitre whatever (see Figs 1 and 2 on Plate). At operation at least five sixths of the total gland was taken away, the part removed weighed 7.81 grammes. The normal weight of the female thyroid gland exceeds 21 grammes. The patient made a dramatic improvement.

Hay (1936) states that thyrotoxicosis can exist without any clinically detectable enlargement of the thyroid gland. I believe the best rule is to assume that the thyroid need not be enlarged but that the diagnosis must be established before a case without enlargement of the gland is operated on for thyrotoxicosis.

### Surgery in Thyrotoxicosis

Can the death rate be reduced by regarding thyrotoxicosis as a purely surgical disease? Nearly all answers are very guarded indeed in their answer to this question. All are agreed that operative treatment of a gland so valuable as the thyroid is to be regretted and hope that medical research may find a better way. In human experience the operative results are such as to challenge every other method of treatment. There are no more brilliant results in the whole realm of medicine and surgery than the thyroid case after successful operation. But there can be a considerable mortality and there can be many operative failures. All writers lay emphasis upon the fact that to obtain uniform success in this operation requires a degree of skill judgment gentleness precision and experience together with a judicious selection of patient and the winning of his or her confidence and co-operation exceeding the care and skill needed in the most delicate surgical operation. Den (1931) in a critical review of the late results of operation for thyrotoxicosis reports comparatively few follow-up studies. In 1930 he published which he investigated in detail results were good. In twenty-eight there was improvement in nine and in eleven benefit in five. The same conclusions can be drawn from similar lines.

## Results of Operation for Thyrotoxicosis

The brilliant results which often follow operation, and some of the published papers, may readily give the impression that nearly 100 per cent cure is attainable. Dunhill (1934) expressly warns us that such is not the case. In order to judge my own results I investigated the cases operated on by me for thyrotoxicosis in Bradford Royal Infirmary during the three years ending July 31, 1937—that is, some months before this paper was written. During this period I performed 218 operations upon 190 patients. Scarcely any cases sent to me were rejected. All types were represented, and many elderly debilitated wrecks were included. Two patients died as a result of the operation, both from acute thyrotoxicosis, 188 out of the 190 left the hospital convalescing satisfactorily. All patients were prepared with Lugol's iodine, and operation time was determined solely by clinical judgment, independently of the basal metabolic rate or electrocardiogram, though these were often taken in the later cases. There were no deaths under anaesthesia. Morphine and hyoscine (in doses carefully adapted to the individual patient) with  $\frac{1}{2}$  per cent novocain, and occasionally some open ether at the beginning, constituted the anaesthetic. This anaesthesia compares very favourably with newer and more popular methods, it does not necessitate any special apparatus, and an anaesthetist was rarely needed. The operation is carried out quietly and deliberately, without haste, after-sickness is not common, and chest complications are practically unknown. The patients were nursed in a ward of twenty-five beds, without a special nurse.

As there was no follow-up clinic I have been unable to trace all cases. One hundred and sixty-two replies were received to a questionnaire and many of the patients were interviewed. Two had died—one two months, the other two years, after leaving hospital—from causes not known. The other 160 replied without exception that they were improved by the operation. Only 107—that is, 67 per cent—were fit for a full day's work, and, even of those, 18 per cent had some minor complaint such as feeling tired at night, occasional dizziness, or rheumatism.

The main interest of this inquiry lay in finding out the reasons why the remaining fifty-three patients (33 per cent) were not equal to a full day's work. Those patients fell into a series of groups: (1) the elderly and debilitated who never would do a full day's work again, (2) those who had never enjoyed good health and upon whose debilitated physique thyrotoxicosis had been engrafted, the cure of the thyroid condition restoring them to their original indifferent health, (3) those with associated diseases, such as arthritis and heart disease, (4) those who could not afford a proper convalescence and returned to a troubled domestic atmosphere, adverse economic circumstances, or even the nursing of sick relatives, (5) those in whom there had been a defect in the operative technique such as leaving rather more thyroid gland than the individual required, (6) a miscellaneous group where the patient refused removal of the second side or retained obvious septic foci, or where not enough time had elapsed for complete recovery.

In private patients the results are much better than in hospital: the original physique is better, operation is performed earlier, and conditions for convalescence are much more favourable. Ample time should be allowed for convalescence, as not only has the patient to recover from the operation and the antecedent debility, but the remaining fragment of thyroid gland has to adjust itself to the needs of the body and the unknown

cause of the thyroid malfunction has to subside. A follow-up clinic is very useful.

Two cases of exceptional interest may be recorded.

## CASE V LOCALIZED MYXOEDEMA

A sea pilot aged 43 suffered from typical thyrotoxicosis developing over two years, characterized by much loss of weight, palpitation, excessive perspiration, hoarseness, cough, occasional depression, tremor, and quick pulse. Subtotal bilateral thyroidectomy was performed. He made a rapid and perfect recovery in every respect except one. Four months before operation two thickened areas had appeared over the front of each shin-bone. These grew somewhat after operation for a few months, then remained steady, and a year and a half after operation grew slightly again. They constitute large patches, each about 7 inches by 7 inches, on the front of the tibia starting  $1\frac{1}{2}$  inches above the ankle, with a raised margin, slightly reddened surface, not tender, not pitting on pressure and causing the patient no inconvenience whatever except from their weight and unsightliness (see Fig 3 on Plate). This case was identified by Dr J T Ingram, who published an article (1933) on circumscribed myxoedema associated with hyperthyroidism. This condition is referred to by Dunhill (1937), and he considers it to be mucinoid degeneration.

## CASE VI JUVENILE PRECOCITY AFTER OPERATION

A girl aged 9 years had suffered for a year from typical symptoms of Graves's disease with exophthalmos. Her pulse readily rose to 160. She had failed to respond to non-operative methods of treatment. Her condition being well controlled by iodine she was cured by a two stage operation in the summer of 1932. I had some misgivings about performing a subtotal thyroidectomy at the age of 9 for fear of interfering with her future development. On the contrary, at the age of 14 this girl might easily have been mistaken for a finished young lady 23 years old, her manner, habits, outlook on life, and physique being those of a modern young adult. Dunhill (1937) refers to juvenile precocity occurring after operation for thyrotoxicosis.

## Summary and Conclusions

The central problem discussed is the high and increasing death rate from thyrotoxicosis. The 1,696 individual deaths occurring in England and Wales in 1936 are analysed. Allied problems such as the sphere of iodine in treatment, early diagnosis, and surgical results are discussed. The general conclusion is that the increase in the certified death rate is due not to a single cause but to several. There is an apparent increase owing to more accurate diagnosis, so that cases in which patients were previously certified as dying from heart disease and many other causes are now correctly classified under the heading of thyrotoxicosis. There is a notable surgical mortality. Delay in surgical treatment until the patient is very ill is a contributory cause. The abuse of iodine as a medical treatment may play an important part. There may be an actual increase in the severity of the disease. These conclusions suggest that the certified deaths are more likely to increase than to diminish in the immediate future.

# LOBAR PNEUMONIA, SUBPHRENIC ABSCESS, DUODENAL FISTULA RECOVERY

BY

SIR ARTHUR J HALL, M.D., D.Sc., F.R.C.P.

Emeritus Professor of Medicine University of Sheffield

GRAHAM S SIMPSON, F.R.C.S.

Consulting Surgeon Sheffield Royal Hospital

AND

J. L. A. GROUT, F.R.C.S. Ed.

Radiologist Sheffield Royal Hospital

(WITH SPECIAL PLATE)

While the complications of a pneumococcal infection may be many and various a series of unexpected events such as occurred in the following case of lobar pneumonia must be rare. It is not unknown for a pneumococcal infection of the pleura to spread down through the diaphragm and cause a subphrenic abscess but it must be exceptional for a separate large collection of pus in the apex of the same pleura to be present at the same time and to empty itself into the air passages. Again while cases have been recorded, especially in children in which after the drainage of a pneumococcal empyema the wall of the neighbouring oesophagus has leaked into the abscess cavity so that food comes through the wound it is doubtful whether there is any record of the wall of the duodenum leaking into the cavity of a subphrenic abscess within forty eight hours of its evacuation.

The man's immediate recovery from the danger of starvation owing to this leakage of food must be largely attributed to the jejunal feeding which for two weeks was the sole means of providing him with food. Happily he has recovered his health and to day seven years later is working full time as a miner at the coal face. It need hardly be said that in the earlier stages of the illness it was not easy to form a clear picture of what was happening. The following is the history of the case.

## Case History

A coal miner aged 21 single was admitted to the Sheffield Royal Hospital under one of us (A. J. H.) on February 15 1931 as a case of right basal empyema following pneumonia. Up to this time he had never had any serious illness. One month previously he developed influenza and went to bed. A few days later he was told by his doctor that he had pneumonia. He was very ill and had a bad cough with a pain in the right side which was at first acute and hurt him on coughing and breathing deeply. He coughed up brownish phlegm often very sticky. Three weeks before admission the doctor said he had got over the crisis but still he continued to cough up foul phlegm and his breathing became more difficult.

On admission he looked ill his temperature was 99 F pulse 125 and respiration rate 36 his skin was moist and pale. He had no pain and was taking food well. On examination his chest showed decreased movement on the right side with absolute dullness at the base behind up to the scapular region with lessened fremitus and diminished breath and voice sounds over this area. Impaired resonance was observed over the right front. The heart was slightly displaced to the left. The right base was needed the same evening and thick pus containing pneumococci was obtained.

The diagnosis of a pneumococcal empyema at the right base being thus confirmed on the following day (February 16) a portion of the right tenth rib was resected under local

anaesthesia in the post axillary line. When opened a large amount of offensive greenish pus shot out with great force. Although a considerable amount was lost about half a pint was collected. A large drainage tube was inserted. There is no record of anything unusual happening next day but a note dated February 18 says: "Very copious discharge from the tube. It is thin watery fluid brownish in colour with patches of sodden lymph in it. It smells sour and offensive like stomach contents. There is very little actual pus." On February 19 the discharge was still thin and copious. On February 20 the fifth day after operation mil and piece of orange found in the dressings showed that there was a fistulous communication with the digestive tract this had evidently begun within forty-eight hours of the operation. For the first two days only fluids leaked through but the opening was now large enough to transmit solid

## RADIOGRAPHIC EXAMINATION

On February 21 films were taken by portable apparatus as the patient lay in bed. A straight radiograph of the chest (Plate Fig. 1) showed the resected right tenth rib and a drainage tube *in situ*. A rather ill-defined upper border of the diaphragm is seen crossing the eleventh rib. The subphrenic angle is occupied by a shadow which extends upwards towards the axilla. Also there is a linear shadow extending obliquely downwards from the apex of the right lung to the middle of the lateral thoracic boundary. This is the edge of a collapsed portion of the lung enclosing a collection of fluid.

Shortly after the above film was taken the patient was given a small barium meal. Ten minutes later some of the barium came out through the drainage tube. A further radiograph was then taken (Fig. 2). In this the stomach is seen to contain barium. The right diaphragm dome begins at the base of the twelfth rib and rises to the tenth rib level. Barium is seen in and around the drainage tube. An irregular spray like shadow seen just to the right of the third and fourth lumbar vertebrae is probably the duodenum. Between this and the barium shadow about the drainage tube there are two small shadows. These lie vertically above one another about half an inch from the right side of the vertebral column. The lower opposite the lower edge of the second lumbar vertebra is less dense somewhat elongated and about half an inch long by a quarter of an inch broad. The upper and denser shadow is opposite the lower margin of the third lumbar vertebra rounded and the size of a small pea. They are linked up to the collection about the tube by two shadows of barium. The dome of the right diaphragm is seen at the level of the tenth rib just at the point at which it has been excised curving across to the ninth rib. Its inner end is indistinct but the general abdominal shadow up to about the eleventh dorsal vertebra can be observed. The spray curved line with a shadow outside it in the right upper part is seen as before. Between this and the dome of the diaphragm there appears to be a considerable area of lung.

It was clear from the radiographs that the fistula was not from the oesophagus nor from any part of the thorax but probably from the duodenum. This explained the sour smell of the discharge (like stomach contents) as noted on February 18 and also the fact that barium did not appear in the tube until about ten minutes after the opaque meal had been swallowed. For the time being however it was not possible to make further investigations as to the exact nature of the lesion which the radiographs had disclosed.

## FEEDING THROUGH THE JEJUNUM

The man's general condition was so rapidly improved owing to leakage of food through the wound that the problem of how to feed him was no longer of immediate urgency. It was decided to try feeding in situ the jejunum. On February 22 the abdomen was opened by one of us (G. S. S.) and a large sized rubber catheter introduced obliquely into the jejunum. The drainage tube was then removed. At the same time removed. During the next two days (February 23 and 24) feeds of milk were administered by the jejunum tube none of which came through the opening at the chest thus

confirming the site of the fistula as above this level. Nothing was given orally. On February 25 a little milk pudding was given by the mouth as a test and it came out at the chest wound. The discharge had now become more definitely purulent.

On the 27th water taken by mouth still leaked through the wound. On March 5 the general condition was improving. There was still some watery discharge with the pus from the wound the edges of which appeared to be partially digested. Air was sucked in and blown out in coughing. He was taking food well by the mouth and only very little escaped through the chest wall. On March 14 he was taking full meals by the mouth none leaked through the wound. The jejunostomy tube was finally removed. The chest wound was still open with a slight purulent discharge. A radiograph taken after an opaque meal showed no track towards the right diaphragm. The shadow in the right upper chest seen on February 21 had become denser.

#### PHYSICAL EXAMINATION OF UPPER CHEST

It was now possible to make a fuller physical investigation of the upper chest. There was an area of dullness in the right axillary region corresponding with the shadow in the radiograph, with tympanic resonance mesial to this. A needle in the right fourth space over this area in the mid-axillary line brought away about 15 ccm of yellowish pus, freely mixed with air. With this evidence of a pyopneumothorax at the right apex, distinct from the collection of pus which had been drained at the right base, a fuller inquiry was made into the details of the man's illness before admission. For much help in this we are indebted to his medical attendant, Dr L. Jago.

#### DETAILS OF ILLNESS BEFORE ADMISSION

The facts were as follows. He began with a typical lobar pneumonia in which both lungs were affected. It ended by lysis. Three days later the temperature began to rise again and empyema was suspected. There was practically no sputum throughout until the afternoon of February 14 (the day before admission) when the man himself states that he suddenly began to spit up foul-smelling yellow phlegm. His breathing became very bad and the phlegm continued to come up in large amounts until about 10 p.m. The next morning he was seen by his doctor who needled the right base and finding pus, arranged for the man to be sent to hospital the same day. It would seem that the doctor's attention had not been specially called to this sudden bringing up of pus on the previous afternoon, about which the patient is very clear.

#### Discussion

From this description of what happened on February 14, the day before admission, there can be no doubt that pus had then burst into the air passages. The collection of pus evacuated at operation on February 16 could not have been the one which had burst into the lung, because its contents were in a state of hypertension and were not mixed with air. On the other hand, the shadow in the right upper chest seen in the radiographs of February 21 (Figs 1 and 2) and the clinical findings of pus and air in this region on March 14 are consistent with the view that it was this apical empyema which had burst into a bronchial tube the day before admission.

The presence of a large empyema in the upper part of the right pleura, which according to the history had burst into the air passages the day before admission, made it difficult to believe that the big tense collection of pus evacuated two days later could have been in the right pleura at the same time. The explanation which seemed to fit all the facts was that the pus evacuated at operation on February 16 came from below the diaphragm and not from above it—in other words, that what on admission was thought to be a basal empyema was actually a

subphrenic abscess of pneumococcal origin in the right extraperitoneal area. On this assumption the occurrence of a fistulous communication with the duodenum became less difficult to understand. The close anatomical relations between the duodenum and this subphrenic area are well known. A duodenal ulcer may give rise to a subphrenic abscess, or a subphrenic abscess arising from some other source may burst into the duodenum.

In the present case, however, neither of these things happened exactly. There is nothing which points to any primary trouble in the wall of the duodenum. The man had never suffered from any gastro-intestinal symptoms previously, although the leak was from gut to abscess cavity. On the other hand, everything points to the pneumococcal origin of the abscess. It followed directly after a definite lobar pneumonia, pneumococci were present in the pus, and there was a coincident pneumococcal empyema in the upper part of the pleura on the same side. The fact that the duodenal leak did not occur until the abscess cavity had been emptied and drained suggests that at the time of operation the abscess had already tracked down and reached the wall of the duodenum, into which it would soon have emptied itself had the pressure not been otherwise relieved. As it was the pressure in the abscess cavity being reduced, indeed becoming negative during inspiration, the relatively greater pressure inside the duodenum after a meal was sufficient to break through the thin remnant of wall between it and the abscess cavity. In fact, what happened in this case was very similar to what happens occasionally in cases of oesophageo-pleural fistula following the opening of an empyema. In these, as a rule, it is the thinned and adherent wall of the oesophagus that gives way and bursts into the empyema cavity when the external pressure is reduced by evacuation of its contents and the internal pressure is increased by the passage of food.

Whether the pneumococci reached the subphrenic area directly from the adjacent pleura or whether they were blood-borne is perhaps more of academic interest than of practical importance. The radiographs show evidence of fluid in the right costo-phrenic angle, but it is not now possible to say if this preceded or followed the subphrenic collection. The most simple explanation is direct infection from the pleura above, though such extension of infection downwards is, as has long been recognized, very rare.

Barnard (1908) saw only one such case, and noted as remarkable that while nearly all subphrenic infections pass readily through the diaphragm to the lungs or pericardium, it is rare for the contrary to occur. He discusses the possible reasons for this, which need not be gone into here. He mentions one case of right lobar pneumonia which was followed by a pneumonic abscess in the right anterior and posterior fossae—probably a lymphatic infection—and one case of localized empyema at the left base which burrowed into the left extraperitoneal cellular space, passing below the external arcuate ligament.

Rischbieth (1911), commenting upon this rarity of direct spread through the diaphragm, illustrates it by the varied and devious other directions in which a long standing "empyema necessitatis" will go before emptying itself. Ochsner and Graves (1933), in a critical analysis of more than 3,000 recorded cases of subphrenic abscesses, together with fifty cases personally observed, give the following figures. In 88 per cent the primary lesion was in the abdomen. In from 3 per cent to 6 per cent the infection was blood-borne from some distant focus, while still less

frequently suppurative lesions in the thorax may extend through the diaphragm into the subphrenic space. This occurred in 2.6 per cent of the collected cases. Musser and Norris (1907) in a review of 13,550 cases say that subphrenic abscess is very rarely a sequel of pneumonia and add that the diagnosis of empyema is usually made.

That in our case the pleura was not directly infected by either of the two aspirations or by the subsequent operation was probably owing to adhesions from a local pleuritis either preceding or secondary to the subphrenic abscess. The rest of the history of the case is as follows.

#### Further History of Case

By March 20 the patient's general condition had improved steadily. The apical empyema which had been filling up again (Fig. 3) began to empty itself more freely, the sputum being now copious, purulent and offensive and increased by lying on the left side. This continued for some time. On April 8 the dull area in the right axilla was again needled but only air was obtained. On April 15 the sputum had become much less. He began to put on weight and was sent to a convalescent home. The discharge from the chest wound was very slight. A radiograph taken on April 28 shows the shadow in the right upper chest to be much smaller. The man was now discharged home.

He was not seen again for three years (August 1934). His condition was then as follows.

He was active and well. He had no cough, his chest expansion was three inches. The cardiac impulse was slightly nearer the middle line than normal. The front of the chest showed very little abnormality. The right side was resonant to the sixth rib in the nipple line in front and was rather hyperresonant just above the liver—possibly some marginal emphysema. He plays a wind instrument in a local band. The liver edge was not palpable. At the right back there was a large depressed scar at the site of the excised rib and dullness with loss of vocal fremitus and breath sounds up to about the lower angle of the scapula. The axillary border was resonant. He had a good colour without any tendency to cyanosis. The fingers were clubbed. He lost his job at the coal face while he was ill and up to this time had been out of work owing to bad conditions. A radiograph (Fig. 4) of the chest taken on September 18, 1934, did not show any remains of the shadow at the right apical region.

In February 1938—that is seven years after his illness—he was again seen by one of us (A. J. H.). He was then in excellent health, working full time at the coal face.

Had the existence of a right apical empyema which had burst into the lung and the subdiaphragmatic situation of the collection of pus been correctly diagnosed at the time of his admission, as it probably would have been had a radiograph been then taken, it is possible that the line of treatment adopted might have been different. It could not have had a more satisfactory end result.

The first of a new series of annual conferences covering all aspects of cremation administration and propaganda will be held under the joint auspices of the Cremation Society and the Federation at Balliol College Oxford from July 22 to 25 under the presidency of Lord Horder.

## AN ANALYSIS OF 350 CASES OF ABORTION

By

R. G. COOKE, M.D., D.C.O.G.

Medical Superintendent, Derby City Hospital

(WITH SPECIAL PLATE)

In view of the frequency of abortion and especially of procured abortion in industrial districts an analysis has been taken of 350 cases admitted to the Derby City Hospital during the eight years 1930-7 and an endeavour made to assess the probable cause in each case. To bring the figures to a round number of 350 eleven cases of threatened abortion in which the pregnancy concerned had been included.

#### Statistical Analysis

Table showing Number of Abortions per Year (1930-7)

1930	9	19	
1931	5	19	
1932	7	19	6
1933	36	19	67

The low figures for 1930 and 1931 were those relating to the first two years after the hospital opened. The large number in 1937 may be due to medical practitioners sending more cases into hospital instead of dealing with them at home on account of the proceedings taken against certain professional women abortionists.

The civil state of the patients was

Married	3
Single, widow, or legally separated from husband	347

In addition a certain number of abortions occurred in married women living apart from their husbands but not legally separated.

#### Number of Previous Children

None	97	Seven
One	82	Eight
Two	63	Nine
Three	27	Ten
Four	3	Eleven
Five	1	Twelve
Six	12	

The highest proportion of presumably natural abortion was in women with no children. The highest proportion of presumably procured abortions was in women who had had four children.

#### Number of Previous Abortions

None	20	Three
One	91	Four
Two	23	

It is probable that the history obtained was not always accurate. Thus in a procured abortion a history of previous abortions might be given in an attempt to divert suspicion.

#### Stage at which Abortion Took Place

Under two months	46	Four to six months
Two to three months	130	Five to six months
Three to four months	124	

#### Attitude of Patients

As a whole the patients gave their reasons and symptoms fully. In 316 cases the condition was described freely, in thirty-four the patient was apprehensive and afraid apart from a transient nervousness which was never was not always present in cases due to a criminal

act that subsequently proved fatal. In several instances the history given on admission was modified later. In other cases, subsequently proved to be criminal abortions, the patient denied interference of any sort, sometimes strenuously and to the end. In some cases, evidently procured, the patient said "she did not think she was pregnant." Eleven patients volunteered the information that they were anxious to have a baby, and were disappointed at the abortion, as they were without children. In one septic case, almost certainly procured, the patient said she desired a baby, as her only child had died.

Some curious causes were ascribed by patients, such as "Seeing a strange dog," "Hearing the howling of a dog in the night," "Nearly seeing an accident," and "The death of a relative" (not a close one). No patient who ascribed such a cause was observed to have any instability while in hospital. It is probable that in procured abortions a history is freely given, but is usually quite unreliable.

### Causes

Analysis of the causes of abortion resulted in the following classification:

Maternal disease and foetal abnormalities	63
Falls, strains, overwork, etc.	30
Personal use of drugs. Probable 5. Certain 8	13
Personal interference	6
Interference by someone else	6
Proved interference by unknown person	4
Undetermined	
(i) Probably natural	57
(ii) Probably procured	91
(iii) Indefinite	80

### MATERNAL DISEASE

In sixty-three cases maternal disease or foetal abnormality was present to such a degree that it might reasonably be assumed to be the main factor in the abortion. In some instances an injury was also described, such as falling down steps, etc.—for example, abortion occurring after a fall, with a retroverted uterus.

### FALLS, STRAINS, OVERWORK, ETC.

In thirty cases a history of some such occurrence was given, apart from any other condition. The usual events were falling downstairs, a heavy day's washing, and moving heavy furniture. In some other cases where a fall was described there was proof that local interference had taken place, and the history given was apparently a feeble attempt to divert suspicion.

### PERSONAL USE OF DRUGS

1 *Probable*—In five cases the presence of vomiting and diarrhoea indicated the probable use of drugs.

2 *Certain*—In eleven cases the taking of drugs was admitted, usually a strong purgative in excess or a large number of 'female pills'. One woman became seriously ill with acute nephritis, but ultimately recovered. Some women openly admitted taking drugs, saying they had had three or four children and considered they had done their share. In two further cases, referred to later, the women described the taking of drugs followed by the use of an instrument.

### PERSONAL INTERFERENCE

In six cases personal interference was admitted, in three of them by means of 'slippery elm' bark. In one of these cases the strip of bark was still present in the cervical canal on admission. In two cases the use of a

knitting needle was described, following the unsuccessful employment of drugs—no injuries were visible. In one case it was said that abortion followed a douche. In some of these cases it appeared probable that interference had been carried out by another person.

One woman attempted to procure abortion by introducing a thin stick of "slippery elm" bark. Nothing happened, and some months later she was delivered of a normal full-term child. A further six months later she was admitted to hospital with a stone in the bladder the size of a hen's egg, which on section was found to have as a core the stick of "slippery elm," which had evidently been inserted through the urethra (Plate, Fig. 3). Another case occurred in which the patient took drugs and then used a knitting needle because she thought she was pregnant, whereas she was not, the amenorrhoea being due to the menopause.

### INTERFERENCE BY SOMEONE ELSE

In five cases interference by another person was alleged. In two cases a solid article such as a crochet hook was stated to have been used, in neither case was there any visible injury. The other three cases were caused by the introduction of the finger of a professional abortionist, by the use of a Higginson's syringe in the vagina, and by drugs "forcibly administered by her young man" respectively. In two of the above cases convictions were subsequently obtained against professional abortionists.

### PROVED INTERFERENCE BY AN UNKNOWN PERSON

Definite injuries were present in four cases, in none of which was any clear information obtainable, either at the time or at subsequent inquiries. Two of these cases proved fatal. They consisted of one case of perforated uterus, one of perforated vaginal fornix, and two cases of lacerated vaginal wall.

### UNDETERMINED

1 *Probably Natural*—In fifty-seven cases no information was forthcoming, but in the absence of anything abnormal there were no grounds for supposing that the abortion was other than natural.

2 *Probably Procured*—In ninety-one cases no information was obtainable, but there were reasons for supposing that the abortion was procured. Rough conclusions were drawn from the history, the attitude of the patient, the presence of pyrexia, a septic uterine discharge, and the knowledge that during the period in question various professional abortionists had been carrying on a very extensive practice. Some women evidently had had procured abortions repeatedly.

3 *Indefinite*—In eighty cases the evidence was indefinite, some being probably natural and some probably procured, the majority perhaps in the former class.

### Pyrexia

The patients' condition in respect to pyrexia was classified as

Present on admission	124	Local cases
Not present on admission but present subsequently	26	
Temperature present but due to some other disease	12	
No temperature	13	

It will be seen that in 124 cases pyrexia was present on admission. In twenty-eight of these it did not recur, and was probably due to some reaction after haemorrhage and to the patients' removal to hospital. In the remaining

ninety six it was associated with uterine sepsis. A further group of twenty six patients developed a temperature after admission with the presence of uterine sepsis. In twelve patients pyrexia was present but was due to other causes—for example pneumonia causing abortion. In 188 cases there was no temperature but thirty three of these patients had a purulent uterine discharge. In one case pyrexia was present with uterine sepsis following abortion apparently due to a bicycle accident some days previously.

It is possible for a natural abortion to be accompanied by a temperature—for instance a natural abortion which occurred in hospital in a patient suffering from heart disease.

#### Course of Illness

Normal course	273	Critically ill	12
Ill	55	Died	10

The table shows that in 273 cases the illness ran a normal course. Fifty-five of the patients were decidedly ill, several of them having various sequelae. Twelve were desperately ill and just escaped with their lives. Of the ten patients who died nine had sepsis; the remaining one had chronic nephritis and died of uraemia. Some of the inquiries into the fatal cases produced an open verdict but these cases were possibly associated with women subsequently convicted.

#### Period in Hospital

The time spent in hospital varied from under fourteen days to over three months as follows:

14 to 23 days	222	1 to 3 months	23
14-28 days	98	Over 3 months	2

The conditions present in patients in hospital over one month were profound anaemia, phlebitis, arthritis, pelvic cellulitis, pelvic peritonitis, septicaemia and pyaemia.

#### Slippery Elm Bark

From inquiries it appeared that the most frequent cause of procured abortion in this locality was the insertion of slippery elm bark into the cervical canal and there is reason to believe that it is a common practice. It may be inserted either by the woman herself or by an abortionist (professional or amateur).

Slippery elm bark or *Ulmus fulva* cortex is derived from a tree found in Central and North America. The bark is separated from the trunk and is dried after the outer corky portion has been removed. It occurs in flat pieces several inches long, a few inches wide, and a few millimetres in thickness. It contains much mucilaginous material which exudes on soaking the bark in water. It is claimed to be of value in the preparation of poultices and as a food in illness and debility. If a small portion be soaked it increases considerably in width (Plate Figs. 1 and 2) which becomes approximately doubled but the same comparative increase does not occur in larger pieces. Probably one or more small pieces are placed in the cervical canal and abortion is procured partly on account of the presence of the foreign body and partly from the dilatation of the cervix following swelling of the bark.

#### Conclusions

From a survey of a series of 350 cases covering eight years it appears that of abortions admitted to hospital in an industrial town some 40 per cent are probably procured.

The history in procured cases is usually true, given, but it is unreliable. The commonest cause of procured abortion in the locality in question is probably the insertion of slippery elm bark into the cervical canal.

Local interference is usually performed with a certain amount of mechanical skill and it is rare to find positive evidence of injury—this would appear to indicate that it is more frequently done by someone else than the woman herself. On the other hand local sepsis is exceedingly common. Uterine sepsis accompanied by pyrexia was present in 35 per cent of the cases and uterine sepsis without a temperature in a further 10 per cent approximately.

Of the patients 20 per cent were decidedly ill and 3 per cent died. All the deaths were due to sepsis except one resulting from chronic nephritis and uraemia.

## THE PATHOGENESIS OF BRONCHIECTASIS\*

BY

F. P. LEE LANDER, M.D., M.R.C.P.

Assistant Physician to the Royal Free Hospital, Registrar to the Brompton Hospital.

AND

MAURICE DAVIDSON, M.A., M.D., F.R.C.P.

Physician to the Brompton Hospital.

(WITH SPECIAL PLATE)

In a recent publication (Lander and Davidson 1933) we put forward a hypothesis in regard to the causation of bronchiectasis and endeavoured to show that mechanical factors played by far the most important if not the sole part in the production of bronchial dilatation, the role of infection being secondary and by no means inevitable. One of the points brought out in this communication was the occasional occurrence of bronchial dilatation in a collapsed lobe during the course of artificial pneumothorax therapy and the fact that such dilatation was appreciably lessened in degree when in consequence of a refill a reduction of the intrapleural pressure was brought about. The object of the present paper is to amplify this point and to show that a similar variation in the degree of bronchial dilatation occurs in clinical cases of clinical bronchiectasis under normal conditions of respiration.

Practically all bronchograms are made when the chest is in the position of full inspiration. This is so with all cases at the Brompton Hospital except those of patients under a general anaesthetic when the picture is usually taken at the moment of complete expiration. It seemed good to us to make a series of bronchograms from cases of bronchiectasis both in full inspiration and in full expiration in order to determine whether any difference could be detected in the calibre of the affected bronchi. Some twenty cases were investigated in this way and in all those in which satisfactory bronchograms were obtained dilated ectatic bronchi could be measured in the same patient under the two conditions. A significant alteration in calibre was observed: the expiratory position showed an appreciable diminution in size of the bronchi in comparison with that seen in the inspiratory position. Such alterations in size were much more marked in ectatic than

in normal bronchi they were, moreover, symmetrical, and were not merely alterations in shape due to pressure from surrounding structures

The lung is a highly elastic organ and its retraction during expiration must be the result of this elasticity, and not of any external pressure from the thoracic cage. Diminution in size of the thorax results not in pressure on the bronchi but in further retraction of elastic tissue in the surrounding lung. Consideration of these facts in relation to the cases under observation has led us to the conclusion that the elastic tissue of ectatic bronchi, so far from being destroyed by disease, is intact and functioning perfectly

### Pathogenesis of Bronchiectasis

The significance of the foregoing observations in relation to the causation of bronchiectasis is considerable. The traditional teaching as to its infective origin is still accepted by the majority of clinicians, although the importance of pulmonary collapse as an aetiological factor is receiving increasing recognition. If infection is postulated as a primary cause it may be supposed to act in one of two ways: (a) by weakening the bronchial wall and the elastic tissue, so that elasticity is diminished or lost and dilatation follows immediately, or (b) by causing actual ulceration of the bronchial wall, leading to complete destruction, the enlarged cavity being thus lined by fibrous tissue and mucous membrane (Erb 1933).

In view of the proof we have just given of the persistence of functional elastic tissue, the first of these hypotheses would appear to be untenable. The second might hold good for a short time while the ulcerated cavity is still not lined by fibrous tissue, since it is known that some tuberculous cavities vary in size with respiration. This, however, is only the case when the cavity has no true wall, and expansion and contraction are therefore only explicable by the elasticity of the lining lung tissue. Furthermore, those tuberculous cavities which do thus vary in size tend in the course of time to become larger, since there is as yet no fibrous tissue to demarcate them clearly from the surrounding parenchyma.

The two cases whose expiratory and inspiratory bronchograms are reproduced were both of long standing

### Illustrative Cases

In Case I the bronchogram of 1928 showed a marked degree of bronchiectasis. A phrenic evulsion was performed in that year and from that day to this the patient has remained well though he still has some cough, with about three ounces of sputum daily. The bronchogram of 1938 shows a degree of

Case I

bronchial dilatation slightly less than that present in 1928, presumably due to the counteraction of the excessive negative pressure by the diaphragmatic hemiparalysis. The expiratory bronchogram depicts a state of the bronchi that is almost

normal, but the inspiratory picture shows a fairly marked degree of dilatation.

Case II is that of a girl of 15 who has had a cough ever since she was 2 years old. A plain radiograph showed a collapsed left lower lobe of such small size as to suggest that the collapse occurred in early life. Bronchography revealed not only bronchiectasis in the collapsed lower lobe but also dilated bronchi in the lingula of the upper lobe. The inspiratory and expiratory bronchograms again show a marked difference in size, not only in the bronchi of the lingula, but also in those of the collapsed lower lobe.

Case II

The diagrams have been made from actual tracings of the original x-ray negatives. The attached scale enables accurate measurements to be made of the calibre of the affected bronchi. Prints of the x-ray films are reproduced in the plate, but the contrast in these is not sufficient to show the details so well as can be done by diagrams.

### Summary

Two cases are described in one of these there is radiological proof of the existence of bronchiectasis for a period of ten years, in the other there is very strong presumptive evidence of pulmonary collapse of thirteen years' standing. Comparative bronchograms in these cases show that, despite the existence of dilatation of the bronchi, the affected bronchi still retain their full degree of elasticity.

The persistence of normally functioning elastic tissue in bronchi thus distorted affords a strong argument against the theory that infection of the bronchial wall is the primary cause of bronchiectasis.

The second International Spa Federation Congress will be held in Berlin during the second half of September. The arrangements are in the hands of the Reichsfremdenverkehrverband, Potsdamer Platz 1, Berlin, to which should be sent notification of intention to attend. The first general meeting of the International Spa Congress will be held simultaneously in Berlin and at some German spa. There will be five subcommittees of the Federation Congress to plan for economic, legal, medical, technical, and tourist and propaganda sections respectively. The proceedings of the first Spa Federation Congress have now been published. This volume of six hundred pages contains the official programme and a report of the various discussions at the Bucharest Congress last year, together with lectures which were then delivered and the papers read on the occasion of the centenary celebrations of the Royal Medical Society of Bucharest and the medical postgraduate course which was held concurrently. The price of the Congress Bulletin is 20s or the equivalent in any other foreign currency which sum should be forwarded to the account of the International Spa Federation at the Hungarian General Credit Bank, Budapest 107, as soon as possible.

## HETERO-LATERAL ECTOPIA OF THE RIGHT KIDNEY

BY

R CAMPBELL BEGG, M.C., M.Sc., M.D.,  
FRCS Ed., F.A.C.S., F.R.A.C.S.

(Johannesburg South Africa)

(WITH SPECIAL PLATE)

This abnormality is rare but is of clinical importance. The chief features are brought out in the following case.

### Case Record

A young man of 31 a keen athlete and in perfect health had been rejected for life insurance five years previously because a trace of albumin had been found in his urine. Examination showed no albumin in the early morning urine and no casts or other pathological findings microscopical or chemical at other times. He was normal generally but palpation of the abdomen was difficult. No kidney could be felt on either side. The blood pressure was 136/80 and the blood urea 42 mg per 100 ccm both figures high for his age. Urea concentration was 2.18 per cent in 95 ccm of urine passed in the second hour urea clearance with urea (Fowweather's test) 76.9 ccm per minute. Blood urea at the end of the second hour was 66 mg again a rather high figure. Intravenous pnelography to exclude polycystic kidneys showed no kidney on the right side and two on the left. He was then examined by cystoscopy and retrograde pnelograms—frontal lateral and stereoscopic. These were the findings.

**Examination.**—Bladder normal ureteric orifices normal the right ureter 20 cm in length the left 27 cm. The left kidney was normal in size and location and also in calyx distribution and formation. It was incompletely rotated the pelvis lying in front. The right kidney had passed over to the left side. It lay below and ventral to the left kidney overlapping its lower third. The pelvis was anterior and small and was divided immediately into three major calices. The lower calices were normal the upper large. The papillae of the latter were however not flattened. Both kidneys were about equal in size and showed good and equal function in the excretion of perabrodil. The whole mass extended from the eleventh rib to just above the iliac crest. The left ureter passed forward over the upper part of the lower kidney and then gradually backwards reaching the bladder on its own side. The right ureter crossed the middle line at the level of the last lumbar vertebra and entered the bladder at the normal place on the right side (see Plate). When the kidney mass was pressed upwards the relative position of the two pelves was altered and this together with the clear overlapping individual shadows, indicated only slight fusion or none between the two kidneys.

There was nothing in these findings to indicate the reason for the albumin though possibly the postural or vascular conditions which may bring this about in orthostatic albuminuria were imitated by the lower or displaced kidney.

### Discussion

Stewart and Lodge (1923-4) in 6,500 necropsies found fourteen horseshoe sixteen solitary and one hetero-lateral ectopic kidney. Morris in 15,908 necropsies found one case of the latter type. If it is permissible to apply these figures to general populations London would have about 14,000 people with horseshoe kidneys 16,000 with only one and 1,000 with hetero-lateral ectopia. Owing to the enhanced susceptibility of abnormal kidneys to disease more of these groups are likely to apply for treatment than similar groups of the ordinary population. Now solitary kidneys may be detected by cystoscopy because of a distorted trigone and only one functioning ureteric

orifice or if the kidney is double two orifices on the same side. Horseshoe kidneys may cause embarrassment but are at least recognized at operation. Hetero-lateral ectopic kidneys on the other hand are not readily diagnosed by either of these methods. The ureteric orifices are normal and the passage of ureteral catheters without radiographs does not help. The two kidneys if not fused are in close relation within the capsule of Gerota and even if two ureters are found it may be considered that they belong to a simple double kidney. Unless the surgeon is aware of the condition the whole of the renal substance may be removed and this has happened on more than one occasion. In no case then should pnelograms or radiographs of opaque catheters be omitted.

The cause of hetero-lateral ectopia especially in the 15 per cent of cases without fusion is not clear but the condition must have its origin when the embryo is little larger than a grain of rice—probably through persistence of the usually transitory direction of the ureteric bud in a dorso-medial direction which would carry the kidney anlage towards the middle and ultimately to the opposite side. Acute lesions such as rupture place these patients in the greatest danger if pnelography be omitted. Those interested in the subject will be able to follow the literature by referring to recent articles by Carleton (1937) and Patch (1937).

## HYPEROSTOSIS FRONTALIS INTERNA (STEWART MOREL'S SYNDROME)

BY

T de LEHOCZKY, M.D.

Lecturer in Neurology University of Budapest

AND

A ORBAN, M.D.

(WITH SPECIAL PLATE)

During the past few years neurologists have shown an increasing interest in the syndrome often associated with the name of Morel and each new publication has made some contribution to our knowledge of its aetiology or clinical features. Schiff and Trelles (1931) were inclined to attribute the disorder to trauma. L. van Bogaert (1930) has brought forth evidence to associate the visual defects with compression of the optic nerve in the bony foramen. There is still however a good deal of uncertainty both as to its pathogenesis and to its status as a clinical disorder. At the 1935 Congress of Pathologists in Oslo Henschen even expressed doubts as to the existence of the syndrome.

### Case Report

Eleven years ago the patient, a woman aged 72 had been ill with a herpes zoster in the left ophthalmic area followed by persistent neuralgic pains. A treatment produced a severe dermatitis and ulceration over the head which healed with extensive scarring. A year and a half later she had entered the lower branch of the left trigeminal nerve. Since that time she has been subjected to numerous forms of treatment—with vaccines opium physiotherapy and psychotherapy—without benefit. She had been getting over during the last ten to fifteen years a peculiarly severe form of the trunk or polydipsia was present. Sleep was interrupted the patient being restless during the night and sleepless and dizzy

during the day. Other symptoms included depression, anxiety, tearfulness, and apathy to her surroundings.

On examination she was seen to be small and obese, her weight being 83 kg (182 lb). The obesity had gradually developed during the past ten to fifteen years in the abdomen, around the pelvis and trunk. The extremities were slender, with proximal adiposity. The distribution of hair was normal. The internal organs were healthy, and the blood pressure was 180/110. The second aortic sound was accentuated. There was a somewhat sluggish reaction of the pupils to light, more especially the left, but the fundus was normal. There was impairment of all forms of sensation over the first division of the fifth nerve on the left side and tenderness over the supra orbital and infra orbital notches. The corneal reflex was brisker on the right. Occasional vasomotor changes were observed over the second and third divisions of the left trigeminal area. Other cranial nerves were normal. There was no muscular wasting, and tonus and reflexes were normal. The patient's mental attitude was characterized by a lack of confidence and by irritability. She was markedly egocentric, all her interests and her activities being claimed by her affliction. She strove to make people around her realize the seriousness of her complaint. Her disease dominated the whole of her thoughts. Concentration, attention, and memory were impaired; her general intellectual level was poor, but her critical faculties were good, though primitive. The alkaline reserve was 54 per cent by volume, the serum calcium 11.2 mg per 100 ccm, and the urinary creatine 59.8 mg per 100 ccm.

**Radiographic Examination.**—A skiagram of the skull taken nine years ago shows a conspicuous thickening of the cranial bones, especially in the frontal area. The same appearance is seen in the pictures taken four years ago (Plate, Fig. 1). The thickening of the occipital bone is now somewhat less pronounced and there is a senile atrophy of the mandible. No abnormality can be detected in the vascular pattern, the sella turcica, the sphenoidal sinuses, and the petrous bone. A skiagram taken one year later shows a more pronounced thickening in the frontal bone above the sinus, with marked enostosis. The frontal portion of the falx cerebri is calcified. The same changes, but more pronounced, are seen in the skiagram taken in 1936 (Fig. 2). Here the sella turcica shows some degree of decalcification.

The above case report corresponds with the Stewart-Morel syndrome of hyperostosis frontalis interna in the following particulars:

- 1 The progressive, symmetrical and diffuse thickening of the cranial bones, most marked in the frontal and less marked in the parietal regions. The anterior portion of the falx cerebri is calcified and there is enostosis on both sides of the frontal bone.

- 2 Obesity of the rhizomelic type, developing during the past eleven years.

- 3 Intractable headaches, especially localized in the left frontal region.

- 4 Inverted sleep rhythm.

- 5 Psychological disturbances: (a) impairment of memory and attention, (b) depression, anxiety, and irritability, (c) personality changes—egocentricity, hypochondriacal trends.

On the other hand our patient gave no evidence of excess of appetite, epileptiform attacks, visual disturbance, or dysuria—symptoms which are occasionally present in this disorder. According to Carr (1936) convulsive manifestations have been observed in 35.3 per cent of the cases on record.

#### Comment

This case is of interest for two reasons. In the first place repeated radiographic examination has shown slow progression of the bony changes. Secondly, the onset of

the symptoms at the age of 61, following a trigeminal herpes zoster, is noteworthy. In this connexion we recall van Bogaert's case, that of a woman aged 62 with bilateral optic atrophy associated with the progressive ossification of the frontal bone. The unilateral occurrence of trigeminal symptoms in our patient is most probably due to the asymmetrical extension of the frontal hyperostosis.

#### Aetiology

Most writers have attributed this disease to a disorder of the fat and calcium metabolism. It is a striking fact, however, that Schiff and Trelles alone have been able to demonstrate a hypercalcaemia. Carr recorded a period of creatinuria in his patients, this also occurred in the present case.

The theory of disordered fat metabolism has been corroborated by Mortimer's (1936) experiments on rats. Mortimer gave the animals the ketogenic factor of the anterior lobe of the pituitary gland. The animals so treated not only became fat but also showed a marked sclerosis of the calvarium. This experiment is of importance, too, in that it localizes the causation of the disease to the anterior lobe of the hypophysis. Stewart (1928) also inclined to a dyspituitary hypothesis, while Morel (1930) found in four patients very pronounced histological changes in the nuclei around the third ventricle. On this basis he localizes the lesion generally to the tuber infundibulum-hypophyseal system, particularly in the posterior lobe of the pituitary body. In association with this conception is Moore's (1935) finding of thyroid disorder in 4.4 per cent of his cases, while Carr described menstrual disturbances in 76.4 per cent.

Can the syndrome in question be considered an independent disorder? Henschen (1936) denies it, since frontal hyperostosis without accompanying symptoms is to be observed in 50 per cent of women above the age of 50. In his own words, "the so called Stewart-Morel syndrome is merely imagination."

In the light of the work carried out by Moore (1935), Mortimer, and others one must suppose that Henschen observed abortive or incompletely developed cases. The early stage of the disorder is well illustrated by Somogyi and Bak's (1937) patient, in whom there was only an early degree of hyperostosis with all the other symptoms fully developed.

Our case, together with the data to be found in the literature, inclines us to the opinion of Schiff and Trelles, according to whom the picture is not at present sufficiently circumscribed to be called a specific disease. We must consider the term "syndrome" correct and justifiable from a clinical viewpoint.

In fifty-eight large towns in Germany there was a 28 per cent decline in the mortality from tuberculosis in 1937, compared with 7.1 in 1936. On the other hand there was a rise in the mortality from tuberculosis in Berlin, the Sicilian towns, and the harbour towns in 1937.

## Clinical Memoranda

## Reviews

Saccular Aneurysm of Left Common  
Iliac Artery

In the evening of December 21 1937 a stout married woman aged 71 was admitted to hospital with the following history

## CASE RECORD

The patient had enjoyed good health until the previous evening when she developed a pain in her back which although not severe caused her to retire to bed earlier than usual. The next day she got up and did her usual work until about 3.45 p.m. when a sudden severe pain occurred in the lower abdomen. Shortly afterwards she sent for her doctor who had her immediately transferred to hospital.

On admission she was very pale and restless was perspiring freely and was suffering from marked dyspnoea. Her temperature was subnormal and her pulse rate 140 per minute and of very poor volume. Examination revealed a large

palpable mass in the left side of the abdomen attended with little tenderness and no rigidity of the overlying muscles. Nothing abnormal was detected on rectal examination. The patient died about half an hour after admission.

The post mortem examination disclosed a large retroperitoneal haematoma in the left side of the abdomen displacing the descending colon forwards and separating the layers of the pelvic mesocolon. Removal of the blood-clot revealed a saccular aneurysm of the left common iliac artery about the size of a hen's egg. There was a well marked constriction of the vessel immediately proximal to the aneurysm. The lateral wall of the sac was found to be ruptured at its proximal end and the anterior wall was split into two layers over an area of about two square inches suggesting that a dissecting aneurysm had preceded the actual rupture. Many atheromatous plaques were present in the aorta, microscopical sections of which showed advanced atheromatous changes with degeneration and calcification but no typical appearances of syphilitic aortitis. Sections showed changes in the vessel wall at the edge of the aneurysm similar to those present in the aorta except that there was no actual calcification.

My thanks are due to Mr J. M. Slater for permission to report this case and to Dr W. McNaughton for preparing the pathological sections.

D. P. BURKITT M.B.  
Cornhill and East Dorset Hospital

RESPONSE OF LIVING TISSUES TO  
INJURY

*The Basis of Tissue Evolution and Pathogenesis* By Albert A. Gray M.D. F.R.S.E. (Pp. 92. 11 illustrations with Frontispiece. 7s. 6d. net.) Glasgow: Jackson Son and Company, 1937.

The late Dr. Albert Gray left the draft of a book which it is believed that he intended to publish some time in 1936. After consultation with Sir Robert Muir and Professor Graham Kerr the manuscript has been edited by Dr. Oliver Gray with the least possible alteration and published in memory of his father under the title of *The Basis of Tissue Evolution and Pathogenesis*.

The theory proposed is based upon the nature of the response which the living tissues make to injury. The question is asked at the beginning: Why should repair or healing take place at all in a living body? It cannot be admitted that it was originally teleological. Evolution by spontaneous variation either gradually or by sudden mutation is rejected as needing such an extraordinary sequence of coincidences that it is utterly improbable. The essay is based upon the hypothesis that the variations which result in evolution are induced variations caused by the response to injury and the repair of tissues. The term "injury" is used by the author in the widest possible sense and includes the idea of stimulus so that it may be repeated repair from the effect of injury what to men constituted an injury has become a stimulus. Thus the response to changes in environment takes the form of induced variation in contrast to the idea of "spontaneous variation" which is rejected. Evolution on these lines is illustrated by the comparative anatomy of the labyrinth, an organ which had been the object of particular study by Dr. Gray. The evolution of the labyrinth is discussed at some length and illustrated by a number of figures taken from the author's book *The Labyrinth of Animals*. The origin of the changes which produce chronic inflammation is also discussed and brought into line with this theory which shows how the qualities possessed by fibroblasts and young epithelial cells have been produced. These were not originally teleological in the sense that they were designed to protect the individual animal though the process ultimately comes to have the appearance of a purposive act.

This study of evolution by Dr. Gray is of profound interest because he insists upon the need for taking into account pathological as well as physiological processes and because he attempts to show that the process of repair in a wound is an epitome of the process of the differentiation of the tissues in the evolution of the race and parallels the development of the embryo which is an epitome of the development of the individual. In pathology the examples chosen are inherited deafness and otosclerosis. Whether the theory proposed is true or not it is at least logical. It has come from one who was an accurate thinker and cautious writer. It embodies the philosophy of comparative anatomy and pathology in a fascinating manner and therefore it will receive the attention as a contribution to the study of evolution. It is unlikely that had the author survived he would have published it exactly in the form in which it now appears. This must disarm criticism and allow for a measure of the defects of style and composition.

## DIGITALIS THERAPY

*The Clinical Use of Digitalis* By Drew Luten, A.B., M.D.  
(Pp 226 16s) London Bailliere, Tindall and Cox  
1936

In this monograph Dr Luten takes as his text the aphorism of Wenkebach that "what helps the individual most is to be taken as the best treatment for him, whether it be possible or not to analyse its action in every detail." This principle applies with special force in the case of digitalis, much is known of its effects upon the heart and circulation, but a great deal remains to be discovered. Not content with admitting the gaps in our knowledge, the author considers in his first chapter a most controversial and fundamental problem—the direct effect of digitalis upon the heart muscle. The well-known evidence from clinical, pharmacological, and experimental sources is dispassionately sifted and the conclusion is reached that digitalis has an effect upon ventricular muscle, many have held this to be true, but orthodox teaching at the present day would hardly go as far as Dr Luten in claiming that "the therapeutic efficacy of digitalis results from the action of the drug upon ventricular muscle," or agree with his implication that ventricular slowing during treatment by digitalis of heart failure with fibrillation is an incidental effect rather than one of primary importance.

Many other matters of interest and clinical value are discussed, in his section on dosage and methods of administration the author rightly insists that in the vast majority of cases digitalis should be given by the mouth, the best preparation being the powdered leaf in capsules, tablets, or pills. While intravenous or rectal administration may be demanded on account of urgency or vomiting, respectively, discomfort and uncertainty of absorption rule out the subcutaneous or intramuscular routes. There is no doubt that such haphazard injections are given far too frequently and often quite without regard to indications for digitalis therapy. Dr Luten's monograph is balanced, thoughtful, and well produced.

## PHYSICAL MEDICINE AT FULL LENGTH

*Precis de Physiothérapie Clinique* By Dr Paul Duhem  
(Pp 604, 165 figures 130 fr) Paris Gauthier-Villars  
1937

This weighty volume is indeed an encyclopaedia of physical medicine, dealing with all the principal physical methods and describing their use in many diseases. So comprehensive is the consideration given to individual maladies that the book almost serves as a treatise on medicine, and it has throughout an essentially clinical character which is valuable in a subject which has at times lent itself to much theoretical speculation. The author Paul Duhem, has for years been dismayed at what he considers to be one of the greatest gaps in medical organization in France—namely, the lack of liaison between specialists practising different branches of physiotherapy which made it almost impossible until recently for a patient needing several kinds of treatment to obtain them under one roof. The patient was obliged to travel from one place to another and be treated by different people for such obviously related processes as x-ray, manipulative, and electrical treatment. Dr Duhem has been at pains to end this failure of co-ordination, and in his *Precis de Physiothérapie Clinique* he has endeavoured to present a broad view of physiotherapy as a whole in order to show the unifying interrelationship which exists between its different branches.

As the book has been based on the personal experience of thirty-five years' practice in a rapidly developing science, it has an engaging and practical interest which should attract both student and specialist. The section on diseases of the nervous system (some 170 pages) describes the most original part of the author's work, and the study of disorders of nutrition is considered from a fresh and stimulating point of view. Among the simpler forms of electrical treatment it is interesting to note that Dr Duhem regrets the passing of the static bath. He regards radiant heat as a wonderful therapeutic agent, but is perhaps somewhat spartan in his use of cold douches when prescribing hydrotherapy. While commending diathermy as the best method of epilation, he has used thallium acetate in ionization with good results, and he describes ionization with histamine, though very irritant, as "specificque des douleurs rhumatismales rebelles." He has more than the usual faith in the Bergonie treatment of obesity. Of short wave therapy he has little to say beyond observing that up to the present it has not cured any more patients than ordinary diathermy. We can find no mention of the success of short waves in furunculosis, but Dr Duhem describes radiotherapy in well-filtered doses as a "marvellous" means of procuring rapid healing.

The author confesses to a certain degree of laziness in using borrowed illustrations for his book. The photographs illustrating the testing of muscle movements are good and are accompanied by clear explanatory remarks. The contents of the book are classified in chapters under headings which in Part I relate to the different physical methods, and in subsequent parts to the different systems and diseases under discussion. The last two chapters are on accidents and dangers in electricity. There is no index arranged in alphabetical order.

## SURGICAL DIAGNOSIS

*Precis de Diagnostic Chirurgical* Published under the direction of Ch. Lenormant. Volume I *Généralités Tête et Cou* By Ch. Lenormant, J. Seneque and P. Wilmoth (Pp 764, 196 figures Paper cover 80 fr, bound 105 fr). Volume II *Thorax Sein, Paroi Abdominale Organes Génitaux Extérieurs* By J. Patel (Pp 490, 138 figures Paper cover, 50 fr, bound, 70 fr). Volume III *Abdomen et Pelvis* By G. Menegaux (Pp 964, 212 figures Paper cover, 100 fr, bound, 125 fr). Volume IV, *Membres* By J. Seneque (Pp 630, 168 figures Paper cover, 70 fr, bound 90 fr) Paris Masson et Cie 1937

*Precis de Diagnostic Chirurgical* is a compact four volume work which has been published under the general direction of Professor Lenormant. It is ambitious in scope, covering general surgery and gynaecology and comprising nearly three thousand pages, which are, however, well illustrated, and, since their subject matter is well grouped and set out, they make by no means tedious reading. The work constitutes the latest of the well known "precis" series published by Masson et Cie, and its various parts are written by Professor Lenormant himself or his pupils—MM G. Menegaux, J. Patel, J. Seneque, and P. Wilmoth. The editor points out that it is designed not for the beginner but for the more mature student and practitioner. In his introduction, which is repeated in each of the four volumes, he quotes a remark of Rabelais, "La Médecine est un farce a trois personnages: le malade, la maladie et le médecin," and this textbook should prove of great assistance to certain of those who have to play one of the parts in the farce, from the chief actor—the patient himself—however, it must be kept, since the illustrations are so graphic that their effects might be disastrous to him and the farce might be turned to tragedy. Most of the

illustrations are photographs and their reproduction is excellent and the same may be said of the majority of the x-ray pictures

Volume I deals with general considerations and with surgical diseases of the head and neck and is written by Professors Lenormant Seneque and Wilmoth volume II the chest abdominal walls and external genitalia is by Dr Patel volume III the abdomen and pelvis by Professor Menegaux and volume IV the limbs by Professor Seneque In a necessarily rather limited work dealing with a vast field it is easy to be critical of the degree of emphasis given to certain subjects and the comparatively brief reference to others Criticism is almost bound to arise no matter how carefully and judiciously subject-matter has been selected by the contributors but after making due allowance for such considerations there are parts which are somewhat disproportionate Thus a picture is shown of a meningococci outlined by lipiodol in an infant of 8 months but a series of good ventriculograms or arteriograms is absent A lipiodol injection in a case of cord compression by secondary carcinoma is shown but the lipiodol appearances in spinal cord tumour and in meningitis serosa are wanting although secondary carcinoma in the spine is unfortunately not uncommon cord compression theretfrom is while spinal tumours and chronic meningitis are not infrequent and their differentiation is important In future editions it is to be hoped that such omissions will be rectified When this has been said there can be nothing but praise for the work It is likely to have an appeal to many other than the pupils of Professor Lenormant and his distinguished assistants and beyond France itself It will make a useful addition to the bookshelf of the consulting surgeon who reads French

### CHEMISTRY OF SEX HORMONES

*The Chemistry of Sex Hormones Tabulae Biologicae* Vol. xv Part I Edited by W. Junk, C. Oppenheimer and W. Weisbach (Pp. 144 Whole volume Fl. 35 reduced price for subscriber Fl. 30) The Hague Dr. W. Junk, 1938

This outline of knowledge concerning sex hormones provides an interesting illustration of the results of the impact of organic chemistry on physiology The chemical nature of the oestrin group was first discovered in 1932 and readers will remember the interest created by the discovery that this hormone was a sterol derivative Soon afterwards it was discovered that the hormone of the corpus luteum and the male sex hormone had a similar chemical composition This group happens to be one which favours the manipulations of organic chemists and the result of their activity is shown by a series of tables now published from Professor Laqueur's department

One hundred and twenty-eight compounds are listed under the title Male sex hormones and their derivatives and the physiological activities of about one half of these have been demonstrated and measured Sixty-nine compounds are included under the head of Substances with oestrogenic activities but this list is really incomplete because it contains only the sterol derivatives and does not include the various simple aromatic compounds which also have been shown to possess powerful oestrogenic activity Forty-six compounds are described under the heading Corpus luteum hormone and its derivatives These figures suggest that members of the sex hormone group of sterol derivatives are developing a complexity comparable to that of some of the groups of dyestuffs and it is evident that the developments in a subject of such

complexity can only be followed by specialists who devote their whole time to such a study

That a subject of this complexity can develop in less than a decade suggests that biological workers will find increasing difficulty in keeping pace with the activities of the organic chemists a development that may call for an increasing degree of organization and collaboration between physiological laboratories The facts mentioned provide a striking proof of the rapidity of the advance in knowledge of the chemical substances which control the sexual functions and it is reasonable to hope that this will lead in its turn to important clinical advances

### YEAR BOOK OF DERMATOLOGY

*The 1937 Year Book of Dermatology and Syphilis* Edited by Fred Wise, M.D. and Marion B. Sauer, M.D. (Pp. 736 110 figures 500 dollars 12 6d Postage 6d) Chicago Year Book Publisher Inc London H. K. Lewis and Co. Ltd. 1938

As usual the editors have produced an interesting volume in which they review the work that has been done in dermatology during the past year In accordance with their usual custom they start with an article of special interest to the general practitioner and on this occasion they devote it to the modern treatment of common fungous affections the importance of which has become well recognized during recent years Their article is full of practical points and we are glad to notice that they warn the reader against making the diagnosis of mycotic infection without adequate reason and they rightly state their opinion that many cases of so-called dermatophytosis and dermatophytids are not of fungous origin at all and hence do not respond to a therapy based on an erroneous diagnosis No very striking advance appears to have been made in dermatology during the past year though there is plenty of evidence of very active work all over the world Many workers have been trying to extend the application of the comparatively recently introduced Grenz rays into dermatology and it appears that these have a very definite place in therapeutics They are much safer than x-rays and in certain cases are more efficient notably in the treatment of very superficial naevi such as port wine stains and also in the rare Darier's disease a complaint which is practically resistant to x-rays From the public health point of view the most important progress to be noted is the rapid spread of measures to the control of venereal disease throughout the United States of America Apparently they have been several years behind this country in adopting a comprehensive scheme for this purpose The editors of the year book regret the absence of provision for inpatient treatment of all patients actively infective otherwise they heartily support the efforts of the authorities We recommend the year book to the attention of dermatologists

### Notes on Books

In our review of the first edition of *The Social Structure of England and Wales* by A. M. CARR-SAUNDERS and D. CARADOC JONES its value was indicated and we were not surprised that a new edition has been required (Oxford University Press 10s) The object of the book is to give a succinct account of the numbers, age distribution, housing, education, occupations, wealth and qualities of the people an account based mainly upon official census data Since the first edition appeared some ten years ago another census has been taken and in this edition the new data are incorporated and in some cases comparisons between the results of the last two censuses are made

It is a monograph on tropical ophthalmology to satisfy, as he explains, the need of the Italian colonial empire for a book of reference on this kind. Such departures from the usual classification adopted in textbooks of this kind are accepted as there are consist of eponyms instead of more accepted international usage. The book is profusely illustrated, and should help to fill a gap in Italian ophthalmic literature. It is published at Milan by Ulrico Hoepli, and the price is 45 lire.

## A DRIP FEED FOR D.A.

Dr T A B HARRIS, anaesthetist to Guy's Hospital, writes

The drip feed illustrated below has been designed to be used on any type of Boyle or McKesson apparatus. It is made so that it can be carried or left attached to the apparatus without fear of the liquid escaping by evaporation or leakage. This is made possible by a revolving sleeve controlled by the larger milled wheel C which in the position 'off' closes both the inlet and the drip outlet when the attachment is not in use.

A standard size bottle of divinyl ether is screwed firmly into the base care being taken to see that the foil covered washer Q is in place. In this position the bottle base and sight feed are suspended vertically beneath the tubular mount.

When required for use, the apparatus is revolved on its tubular mount through 180 degrees and is held in place by the screw R. The sight feed is now in free communication with the tubular mount with the bottle standing inverted above the mount. The larger milled wheel C is then turned counter clockwise to the position on'. This opens the inlet thus equalizing the air pressure, in the bottle above the fluid and in the tubular mount and sight feed and allows fluid to enter the drip outlet. The rate of drip is then regulated by means of the smaller milled wheel D which turned counter clockwise, increases and turned clockwise, decreases the rate. Anaesthetic fluid drips through the glass chamber Q on to a metal gauze (I) in the tubular mount, where it is vaporized.

by respiratory gases. The rate of drip  
it can be interrupted at will by means of the mini-  
without altering this adjustment

I have used this attachment for the past eighteen months with  
satisfactory results mostly for divinyl ether but also for ether  
and chloroform. It is especially suitable for closed anaesthetics,  
for fluids are volatilized without resistance to breathing.

It has been made to my instructions by Coxeter and Son Ltd,  
Morden Road London SW 19

**AND NASAL ATOMIZERS**

Company new throat a  
tentative adjustment

**THROAT AND NASAL ATOMIZERS**

**THROAT AND NASAL ATOMIZERS**

We have received from the Gardner Company new throat and nasal atomizers. One type of atomizer has a patented adjustable jet and shield both are so firmly attached that there is no danger of the shield slipping off when the spray is released and the spray can be directed upwards or downwards through a range of some 90 degrees. The retail price of the atomizer is 5s 9d. Further details may be obtained from the manufacturers at 7, Chapel Street, Milton Street, London E.C.2.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY MAY 14 1938

## THYROTOXICOSIS

The awakening of the medical profession of this country to the importance of thyrotoxicosis or hyperthyroidism has come from various sources. We may recall that in this *Journal* eighteen years ago J Strickland Goodall and Lambert Rogers<sup>1</sup> pointed out the paramount importance of the cardiac condition in the disease and strongly advocated surgical treatment—subtotal thyroidectomy—because they were convinced that it offered the best means of success. Surgical treatment which had fallen into abeyance owing to the difficulties of anaesthesia and disastrous toxic after-effects of operation was re-established as a reasonably safe procedure by Berry Dunhill and Joll. The new teaching spread to practitioners throughout the country they became more alive to the facts and their diagnosis was thus improved. These features alone cannot fully account, however, for the increase in the number of cases reported, and the evidence would show that the disease is more prevalent. In a careful analysis of the Registrar-General's figures made by Mr Peter McEwan and reported elsewhere in this issue it is shown that there is a high and rapidly increasing death rate. During the year 1936 no fewer than 1 696 deaths were attributed to thyrotoxicosis in England and Wales, and of these some 60 per cent had some form of heart trouble. McEwan's analysis of the homes of these patients leads to the conclusion that there is a very varied distribution of cases throughout the country and that the incidence is highest in the mountainous regions of Westmorland and Mid Wales and in Huntingdon. Among the aetiological factors in thyrotoxicosis the stresses of life have been emphasized. These can hardly be great in the country districts named certainly not as great as in the towns and thickly populated areas and it may well be that the in-breeding prevalent in these regions has a tendency to bring out the hereditary factors. Nevertheless many shrewd and competent observers are convinced that the stresses of life do play an important part for instance, Dunhill<sup>2</sup> writes. The frequency and the extent of emotional disturbance among these patients surprise me. It may be that in

certain districts soil conditions may conduce to sub-efficiency of the thyroid gland. Campbell's survey of the geographical distribution of the death rate during the years 1913-19 shows a close parallelism with McEwan's figures and Campbell concluded that there was some degree of correspondence between the incidence of simple goitre and of the thyrotoxic deaths. Dunhill may be quoted again as stating that very few patients who carry a simple goitre into middle life escape the development of toxic symptoms.

Thus it may be profitable to argue that the death rate would be reduced by timely operation on simple goitres or goitres that are in the early stages of toxicity. Before passing judgment on this however it is necessary to discuss two further points: first are the statistics a complete statement of the occurrence and death rate of thyrotoxicosis<sup>3</sup> and secondly are therapeutic measures other than surgery available and adequate? The term thyrotoxicosis introduced when an altered secretion or dysthyroidism was postulated remains a convenient generic term to cover a number of manifestations of hyperthyroidism and to bring under one heading the varied nomenclature without defining the underlying pathology. There is much to favour the adoption of the term toxic goitre since it should be insisted on that in thyrotoxicosis there is always a goitre though it may not always be obvious. Pursuing his interpretation of the underlying pathology Dunhill has remained an advocate of the essential unity of toxic goitre. Thus the only masked thyrotoxicosis is where the goitre is situated behind the sternum and can only be revealed by x rays or surgery. The varied clinical manifestations are to be regarded as complications not masks. Digestive disturbances of stomach and bowel emaciation mental instability, and above all heart symptoms may dominate the picture but in all there is the central toxic goitre. The cardiologists have especially insisted on thyrotoxic cardiovascular phenomena—irregularity of the heart especially auricular fibrillation hypertension and angina<sup>4</sup>. Thyrotoxicosis is however not an oasis with a central toxic goitre as a well situated in an unrelated desert. It is distinctly engrafted on a soil that takes a share in the resulting phenomena. Thus in the *formes frustes* there is a gradual series to which goitre and patient contribute as variable factors radiating outwards from frank<sup>5</sup> thyrotoxicosis to neuro-circulatory asthenia to neurosis to mental instability to digestive disturbances to cardiac failure apart from thyrotoxicosis to emaciation so that at the periphery no element of thyrotoxicosis is present.

## THYROTOXICOSIS\*

Because of this there is an important medical aspect and function in diagnosis and treatment. Early recognition followed by rest and nursing may arrest or retard deterioration, but the most careful supervision is necessary, since the patient may quickly slip back. There is a place, too, for iodine in medical treatment. Its use in surgery may be shown in the widely published views of Pemberton from the Mayo Clinic that the total death rate during the period before iodine was used in preparation for operation was at least eight times greater than it is to-day. Sound medical opinion is that the use of iodine obstructs the delivery of the thyroid hormone to the body at any stage of the disease, and may thus hold control while the stimulus to the production of the hormone has time to subside. For iodine affects not the course but the intensity of the complaint, and appears to be useful at any stage. Indeed, apparent iodine resistance may mean that the disease is increasing too rapidly in severity.

Authoritative surgical figures show that 60 to 70 per cent of patients are able to resume normal life and work, and that over 80 per cent of cases of auricular fibrillation regain normal rhythm. But in McEwan's analysis operation was stated to be the cause of 276 of the 1,696 deaths reported in 1936. On the other hand, there are under 3 per cent of deaths over a series of all sorts of cases, often very severe, when the preparation, the technique, the division into stages and the after-care are thoroughly planned. They would seem to be worth while. It is necessary to judge which cases are due to toxic goitre and will therefore respond to surgery. With accompanying heart disease, irregular rhythm and congestive heart failure, far from being contraindications, are really strong indications for operation. The operation of complete thyroidectomy in all cases of congestive heart failure is, however, not rational, good may be done to many, perhaps to more than we think, but not to all. These clinical problems of thyrotoxicosis deserve ventilation, and careful balanced work such as Mr McEwan presents is needed, and welcome.

## THE ADRENO-GENITAL SYNDROME

Dr H W C Vines and Mr L R Broster, together with their collaborators, are to be congratulated on an admirable step in the elucidation of the complicated subject of the adrenal cortex and intersexuality. It was a fortunate circumstance that Dr Vines was able to establish a definite fact as

a starting point for this research—namely, the association of a fuchsin-staining cell with virilism. This observation, which has been confirmed, can now be accepted as proved, and it affords a touchstone by which theories can be tested. With its aid progress became rapid. The whole research is an example of successful teamwork involving the consulting-room, the operation theatre, and the laboratory, as the plan of this monograph shows, and Sir Walter Langdon-Brown brings out this point in his foreword.

The first part is devoted to a clinical study of the adreno-genital syndrome, the physical and surgical section by Mr Broster, and the psychological by Dr Clifford Allen. There is a full account of the technique and results of the operation of unilateral adrenalectomy as worked out by the former, and the correlation of the physical and psychological aspects of virilism has led to some useful results. Such abnormalities may be either endocrine or psychological in origin, while often both factors are involved. The evaluation of the extent to which either is responsible must have an essential influence on the type of treatment to be adopted. It is a familiar fact to all physiologists that any departure from normal sexual development produces a degree of psychological disturbance and distress which is quite incommensurate with the physical abnormality. Nor is the injury confined to the victims alone, their influence in the community must also be taken into account, as the scientific study of delinquency is daily showing more clearly. The second part of the monograph is devoted to laboratory studies. Here Dr Vines gives an account of the histology of the syndrome, which is followed up by two investigations on the biochemical side, one by Dr Jocelyn Patterson and Dr Alan Greenwood, the other by Professor Marrian and Mr Butler of Toronto. It is this all-round approach to the subject which gives the study its particular value.

There is to-day general agreement that virilism in women may arise from one of three main causes—pituitary, adrenal, or ovarian, the pituitary disturbance usually involving the basophil cells. Since Professor Woollard threw doubts on the specifically gonadotropic function of these cells there has been a change in our interpretation of some of the features of Cushing's syndrome. While Crooke has shown that the essential characteristic of the syndrome is a hyaline change in these cells, it has also been found that thyroid growths can lead to the condition, by some means as yet unknown. In other instances the adrenal changes far exceed the pituitary ones. Thirdly, virilism may result from a tumour of the testis or the ovary, the arrhenoblastoma, which sometimes

*The Adrenal Cortex and Intersexuality*. L R Broster M Ch, H W C Vines M D, Clifford Allen M D, H W C Vines M D, Jocelyn Patterson M Sc, Ph D, Alan W Greenwood Ph D, D Sc, G F Marrian D Sc, G C Butler B A (Pp 1091 37s 6d). Chapman and Hall 1938.

simulates the structure of seminiferous tubules. This has emphasized the bisexual nature of the ovary and we are led to the view that the influence of the pituitary basophil cells normally inhibits the androgenic cells already existing in that organ. Virilism of pituitary origin then is of the nature of a release of androgenic factors in the ovary. Primary adrenal virilism on the other hand by increasing the fuchsinophil cells in the gland positively increases the androgenic factor though as shown by Achard and Thiers as long ago as 1921 both pituitary and adrenal factors may be involved. This was confirmed by Parkes Weber's case reported in 1926 and included in Cushing's original survey in that case there was a small basophilic adenoma in the pituitary with adrenal cortical hyperplasia. But in such cases it would appear likely that the pituitary changes are primary so great is the influence of the pituitary on the other endocrine glands. In this monograph by Mr Broster and his fellow workers the general principle is laid down that the occurrence in the female during early foetal life of a short period of androgenic heterosexual development of adrenal cortical origin introduces an element of instability in the female which is rare in the male. It is generally admitted that the earlier in life that such heterosexual elements increase the greater the physical abnormality while with later changes the psychological abnormalities predominate. We are left with the conclusion that feminism in males is purely psychological except in the rare instances of an included female twin forming a teratoma.

The thanks of the profession are due to Lord Wakefield of Hythe whose generosity has made this valuable addition to medical knowledge possible.

### A PNEUMONIA EPIDEMIC

Primary pneumonia is a notifiable disease in this country wherein presumably it is recognized as being communicable. Infection with a virulent pneumococcus from an extraneous source is usually assumed to be one of the factors in its origin but the established disease is not infectious to any degree warranting the accepted use of this term. Nevertheless it does occasionally assume epidemic form and an extensive outbreak of this kind with several points of unusual interest is recorded by W G Smilie G H Warnock and H J White<sup>1</sup>. It occurred in the State Mental Hospital at Worcester Mass. which has a population of 2400 patients and 600 staff and was preceded by an epidemic of influenza the pneumonia which followed however was primary and did not arise as a complication of an attack of influenza in the individual case. In all nearly 100 cases of pneumonia occurred over a period of eight weeks the great majority

of which were of the lobar type and proved to be due to a Type I pneumococcus. From the fact that they arose in many different parts of the hospital it appeared likely that this pneumococcus had become widely distributed and this assumption was confirmed by nasopharyngeal cultures from a random sample of the population fully 10 per cent. were carriers. The identification and isolation of all the carriers of whom there must have been at least 200 was considered impracticable and it was decided to try to check the epidemic by active immunization of the entire population. It will be remembered that studies have lately been made in the U.S.A. of immunization with preparations of pneumococcus polysaccharide. It has been shown by Felton that a single injection stimulates apparently adequate antibody production. Proof of actual protective power is naturally difficult to obtain in ordinary circumstances since the likelihood that any significant number even among some thousands of people will develop pneumonia within a given period is small. In circumstances such as those existing at this hospital the liability was great. Following almost universal treatment with a single dose of Felton antigen there was a sudden fall in the incidence of pneumonia of the few further cases which occurred only four were of Type I and all but one of these were in individuals among a group of 200 who had refused the antigen. At a late stage in these events a branch hospital which until then had escaped became involved in the outbreak and there were good reasons for attributing this to the transfer of a single patient who conveyed the infection from the main hospital. The experience already obtained was here repeated on a smaller scale with the important difference that the outbreak was apparently checked after only a fortnight whereas argument by analogy would justify an expectation that if unhindered it would have continued longer. In the absence of an adequate proportion of control cases these observations are not fully conclusive but they amply justify resort to this method of immunization whenever the rare and serious emergency of a pneumonia epidemic should arise.

### PREMEDICATION FOR TONSILLECTOMY

Questionnaires though a source of legitimate annoyance to busy hospital superintendents and practitioners serve as a convenient means of collecting statistical information if due allowance be made for the personal factor. On the whole they appear to be more widely used in America than in this country. An interesting survey concerning the use of pre-operative medication for tonsil and adenoid operations in thirty American hospitals has recently been made with the aid of questionnaires by H D Harlowe<sup>1</sup>. Of the 140000 operations reported in about 90000 some form of pre-operative medication was received. The number of hospitals using premedication as a routine was sixteen (approximately 50 per cent.) five hospitals (20 per cent.) used premedication to some extent and nine (20 per cent.) not

<sup>1</sup> *Bulletin of the National Association of Nurse Anesthetists*, February 1933.

at all. The surgeons in the habit of employing pre-operative drugs agreed that these were a definite aid in the anaesthesia. In a three-year period no serious complications were attributed to their use. The author's personal experience is based on a series of 250 tonsil and adenoid operations prior to which atropine, atropine and codeine, atropine and nembutal, or atropine and morphine had been administered. The observations were compared with those in a control series of an equal number of operations without pre-medication. The surgeons, anaesthetists, and nurses were invited to record their impressions carefully in each case. There was general agreement that with pre-medication induction of anaesthesia was shorter, the anaesthesia itself smoother, and less anaesthetic was required, and that the children behaved better after the operation. On the whole a combination of atropine with nembutal ( $\frac{1}{2}$  to  $1\frac{1}{2}$  grains from 6 to 16 years) was found to give the best results.

### MENIÈRE'S DISEASE

An important contribution to our knowledge of the pathology of Meniere's disease comes from the Otological Research Laboratory of the Johns Hopkins University,<sup>1</sup> based on a study of ninety-four patients with severe and intractable vertigo who were cured by intracranial division of the vestibular nerve. According to Dr Crowe it is a mistaken idea to look upon this brain operation as a terribly severe one. There is a great difference between the removal of a brain tumour and the operation for the cure of Meniere's disease. In one the intracranial pressure is increased, while in the other there is no change at all. In 90 per cent of the cases the disease was unilateral and the hearing in the affected ear was markedly impaired. The entire auditory nerve was cut in forty-nine cases, curing the vertigo but destroying what hearing was left. The necessity for preserving hearing, however bad, in the occasional case with bilateral Meniere's disease, or bilateral deafness from other causes led to the development of the ideal operation—division of the vestibular nerve alone—and this was done in forty-five cases. The vertigo is nearly always associated with tinnitus. Anatomically the only region where a single lesion could cause these two symptoms is in the membranous labyrinth where the vestibular and cochlear end-organs are bathed by a fluid common to both—the endolymph. Vestibular tests should be done in patients with Meniere's disease as part of the clinical investigation. Dr Crowe employed only the milder caloric test, because the rotation test may precipitate an attack of vertigo—so much dreaded by the patient. Nearly 30 per cent of the cases gave no vestibular response on the affected side, this is usually interpreted as pointing to a destructive lesion. Yet these patients with no vestibular response whatever, and whose chief complaint was vertigo were all cured when the vestibular nerve was cut, proving the inconsistency of the vestibular tests. If the symptoms of Meniere's disease were

caused by a lesion which destroyed the labyrinth or the nerves, they would be self-limiting. But many of the author's patients had had attacks of vertigo for fifteen or twenty years, and only an irritative lesion could cause symptoms over such a long period. A history of "whirling of surrounding objects" during an attack is most important in differentiating between the dizziness of Meniere's disease and that resulting from other conditions. The similarity of the symptoms of Meniere's disease to those produced by artificial stimulation of the labyrinth is evidence that this disease is due to a lesion in the static labyrinth, and not in the nerve or central vestibular pathways. If the symptoms of Meniere's disease were the result of a disordered metabolism of fluids (Mygind) or of sodium (Furstenberg), it is difficult to understand why such a disorder should affect one side only, and why division of one vestibular nerve cures patients whose dietary habits remain unchanged. Nevertheless, it is doubtful whether the metabolic theory can be dismissed so easily. If the symptoms of an irritative lesion of the membranous labyrinth are removed by cutting the vestibular nerve, the same must apply when the vertigo is due to oedema of the membranous labyrinth, or to an irritation of the nerve endings by excessive sodium ions. And the difficulty of accepting a unilateral irritation is the same whatever explanation of the pathology is put forward. Dr Crowe firmly believes that the vertigo and deafness of Meniere's disease are always caused by stimulation of, and degenerative changes in, the peripheral auditory and vestibular structures, most likely the result of pressure or chemical changes in the endolymph. It is impossible to have vertigo after section of the vestibular nerve, and the cure of the disease is due to this fact.

### CANNABIS INDICA

The pharmacology of *Cannabis indica* has been providing copy for the daily press in various ways. Since 1937 a great craze for hemp smoking has spread up across the United States from Mexico. Peddlers have sold it to young people under the name of "marihuana" or "Mary Warner," or it has been made up into cigarettes, which are known as "reefers." Numerous crimes have been attributed to marihuana, and special legislation has been introduced against its distribution. Nothing comparable with this has happened in this country, but cases do occur. The hemp seeds which are sold for feeding birds will sometimes germinate and grow in England, and not long ago a young man intoxicated himself with hemp grown in an English garden. Marihuana was blamed for the crimes of one of the soldiers involved in the recent shooting affray at Barkingside. Various different kinds of hemp were recognized at one time, but it is now thought that there is only one species and botanists do not distinguish between *Cannabis indica* and *Cannabis sativa*. The plant is an annual herb, which is usually three to six feet high, but may grow to eighteen feet. It is closely related to the flax. Its original home was Central Asia, but it has been spread by man all over the world. It is grown as a crop

<sup>1</sup> *Medicine* 1938, 17, 1

China Russia Southern Europe the United States and Chile for the sake of its inner bark or bast which is used for making twine harness thread carpet warp canvas sails and rope. The drug is prepared from a resin which is found on the flowers and stems and from the leaves and may be chewed swallowed or smoked. It was at one time included in the *Pharmacopoeia* as a hypnotic but was found to be too variable in activity. The active principle has not been isolated and the only method of determining whether a given sample is active or not is to test it on man or on animals. In some ways its action is like that of alcohol: it diminishes self-control and gives a feeling of exaltation and increased power. It has a curious action on the sense of time like that of the New Accelerator or H. G. Wells though less potent so that minutes seem like hours and hours seem like days. Dance band musicians find that when they have taken hemp the beat seems to come quite slowly to them so that they have time to interpolate improvised notes with comparative ease. The results of a careful investigation of the effects of hemp on a group of patients in the Pretoria Mental Hospital<sup>1</sup> have recently been published. It was found that the effects could be classified into several stages of intoxication. In the first stage the patients were mentally dull in the second silly and fatuous in the third emotionally unstable. After this some patients became irritable and pugnacious while others became depressed. The final stage was always one of deep sleep. There were surprisingly few after-effects. Addicts often show moral and mental degeneration but it is difficult to say whether this is the cause or the effect of the addiction. Murders suicides and sexual assaults have frequently been attributed to hemp and the word assassin which was first applied to a Muslim sect of the time of Saladin is said to be derived from the fact that this sect was in the habit of committing secret murders under the influence of hemp which is known as hashish in Arabic. In a recent paper which deals with the wave of hemp addiction in America Yawger<sup>2</sup> throws doubt on the theory that hemp leads to crime. A number of sensational cases have been reported but none of them has been fully analysed and Yawger doubts whether *Cannabis indica* is as potent an instigator of crimes as alcohol.

### AQUATIC LIFE

A pamphlet belonging to the Economic Series of the Natural History Museum has been prepared by Dr Anna Hastings for the better guidance of visitors to the extended exhibit at the Museum on the subject of water biology.<sup>3</sup> Among the forms of plant life which enter waterworks the green algae the blue green algae and the diatoms are described and species illustrated. Among the numerous animal invaders reference is made to the sponges rotifers and molluscs the planarian and oligochaete worms the crustaceans including *Daphnia* together with midge larvae stick-

lecks and cels. Algae and diatoms are abundant in rivers and crustaceans few. In reservoirs on the other hand all are strongly represented. Active plant proliferation in reservoirs is in general preferred to animal yet the animal type may sometimes serve to check superabundance of the plant as was shown lately when the removal of mussels from the walls of a reservoir was promptly followed by the appearance of excessive swarms of algae. These forms indeed may on occasion multiply beyond all reason. In 1931 *Oscillatoria* caused the water in a London reservoir to resemble cocoa and stained the filters so roval a purple that the whole system had to be put out of commission for several months. Normally however the algae render excellent service in waterworks by forming the biological film on the surface of sand filters which strain pathogenic and other bacteria out of the water though sticklebacks and midge larvae may at times mar the result by boring through the film and so causing unpurified water to pass into supply. In connexion with the present day use of traces of copper to control algal growth Dr Hastings cites the view of a Sanskrit author who wrote in 800 B.C. to the effect that it is good to keep water in copper vessels. In support of storage as a means of purification she recalls that Professor P. Frankland said:

The leap over Niagara leaves bacteria unscathed but they quickly disappear in the still waters of Lake Ontario. This compendious and pleasant brochure presents well chosen information which will be of interest to both purveyors and consumers of drinking water.

### PAROXYSMAL HYPERTENSION

Although one of the rarest diseases known the paroxysmal arterial hypertension associated with benign tumours of chromaffin tissue continues to excite interest probably because it has the distinction of being the only condition in which there is fairly precise evidence as to the causation of raised blood pressure. The condition was first described by L. Abbe Tinel and Doumer in 1922<sup>1</sup> and eighteen cases in all have since been reported: these are the subject of a recent review by Howard and Barker. The malady is characterized by attacks in which the arterial pressure rises to a level which may exceed 300 mm Hg for the systolic and 240 mm Hg for the diastolic readings. Between the attacks the blood pressure is usually normal in the early stages but later tends to be raised. The attacks themselves are often of a dramatic nature. They begin with palpitations paraesthesiae in the arms intense headache or severe pain across the chest. The skin becomes blanched or presents an ashen cyanosis the patient looks anxious or gravely ill. Intense constricting pain in the chest or epigastrium is common and also severe headache. The attack usually lasts for an hour or two and leaves the patient severely prostrated. Death occurred from acute pulmonary oedema in five patients during an attack. In every instance benign tumours of chromaffin tissue

<sup>1</sup> *Bull. Mem. Soc. med. Hop. Paris* 1922 46 932.  
<sup>2</sup> *Johns Hopk. Hosp. Bull.* 1937 61 371.

so called phaeochromocytomata, were found in the abdomen at operation or at necropsy. In most cases the tumour was situated in the medulla of the suprarenal gland, but in some it was distinct and in one case lay lateral and superior to the hepatic flexure of the colon. The size of the tumour varied from that of a cherry to that of a grapefruit. It is certain that in this disease the characteristic attacks result directly from the presence of the chromaffin tumour, for in nine cases in which the tumour was successfully removed at operation the attacks abruptly ceased. Since chromaffin tissue is the tissue which secretes adrenaline, it is natural to ascribe the attacks to the release of large quantities of this substance from the tumours. The behaviour during the paroxysms is not inconsistent with what we know of its action, but there are phenomena, such as the intense thoracic and abdominal pain and acute pulmonary oedema, which have never been produced in man by injection of adrenaline. It is, however, probable that the amount released from the tumours during the paroxysms is far in excess of the dose which even the boldest experimenter has yet dared to inject into his human subject. In this connexion it is of interest to note that the adrenaline content of the tumours has been estimated in five cases, in one it was within the normal range at 6.7 mg, but in four others the amounts were enormous, being 240, 275, 285, and 300 mg respectively.

### VITAMIN K

When chicks are fed on a diet deficient in certain fat-soluble compounds but adequate in respect to vitamins A, B<sub>1</sub>, B<sub>2</sub>, C, and D, and in total fat and cholesterol, they develop internal, subcutaneous, and intramuscular haemorrhages. This bleeding is associated with and apparently due to a fall in the amount of prothrombin in the blood. It can be cured by administering a substance found in the unsaponifiable non-sterol fraction of hog liver fat and in alfalfa. This substance is named provisionally vitamin K by Dam and his co-workers.<sup>1,2,3,4,5</sup> Dogs which have a biliary fistula suffer from a shortage of prothrombin. Since bile acids are necessary for the absorption of fats and sterols from the intestine, it may be that this shortage of prothrombin is due to the non-absorption of the fat-soluble compound, vitamin K. This factor cannot, however, counteract the haemorrhagic tendency in animals fed on spoiled sweet clover hay, which Roderick<sup>6</sup> and Quick<sup>7,8</sup> have shown to be apparently dependent on a deficiency of prothrombin. Vitamin K is found in hog-liver oil, cabbage, spinach, tomatoes, and alfalfa. It is not found in cod-liver oil or in wheat-germ oil. It is not easily prepared from these substances in a state of sufficient concentration for therapeutic use but fish meal freed from fatty

material by extraction with ether and allowed to putrefy forms a good source of this factor, which can be extracted from it by petroleum ether. The yield of oily extract is about 1 c.c. per lb. of fish meal. The activity of the product was demonstrable on chicks when quantities of 10 mg. were added to each kilogramme of food. Almquist<sup>10,11,12</sup> prepared a crystalline distilled product with protective activity when given as 2 to 4 mg. per kilogramme of food. The material contained no nitrogen, phosphorus, or sulphur. Its molecule contained an aromatic nucleus but not a sterol ring. Almquist found it to be alkali-labile but fairly heat stable. Apparently it is optically inactive and has a molecular weight of about 600. Ultra violet light and absorption materials such as aluminium oxide and magnesium oxide destroy its activity. The determination of vitamin K in foodstuffs must be made biologically. Chicks are fed on a vitamin K deficient diet for three weeks. Blood samples are taken and the plasma is diluted with Ringer's solution and caused to coagulate by adding enough of a clotting agent to make the clotting time normal. The substance whose potency is to be determined is then given to the chicks for several days and blood samples are again tested for clotting time. Clinical trials have been made of preparations of vitamin K whose potency had been determined by experiments on chicks. The doses used by Butt, Snell, and Osterberg<sup>13</sup> were 200 mg. of a preparation of which 23 mg. should be sufficient for a human adult as judged by a comparison of body-weights and food intake of human adults and chicks. Human bile or doses of bile salts (1,000 to 4,000 mg. of "bilron Lilly") were given with the vitamin K extract, the bile being given (in pineapple juice) by mouth or through a tube directly into the stomach or duodenum. Eighteen patients who had obstructive jaundice have been so treated, several as a prophylactic measure. Where the prothrombin time was already high a rapid decrease was obtained by the treatment. Vitamin K given alone to a patient who was not taking food by the mouth was ineffective, but when bile and vitamin K were given together there was a fall in the prothrombin time within twenty-four hours. Bile alone has frequently been effective in controlling bleeding in jaundiced patients who still eat normally. It is concluded that a normal diet contains vitamin K, or this factor may be formed by the action of putrefactive intestinal flora on the food. By the aid of the bile the vitamin K is absorbed. There is, however, no information yet as to how the vitamin affects the prothrombin content of the blood or the activity of the prothrombin in the phenomenon of clotting.

The next session of the General Medical Council will open on Tuesday, May 24, at 2 p.m., when the President, Sir Norman Walker, M.D., will take the chair and deliver an address. The Council will continue to sit from day to day until its business is concluded.

# SURGICAL PROCEDURES IN GENERAL PRACTICE

*This is one of a series of articles contributed by invitation*

## TREATMENT OF OTITIS MEDIA

BY

WYLLS FORMBY, F.R.C.S.

Chronic Catarrhal Otitis Media

This is an insidious sclerosis of the middle ear often referred to as dry catarrh causing deafness of varying degree which is almost always progressive. Frequently the ear condition is associated with definite pathological changes in the upper respiratory passages but in some instances no such changes can be discovered. In other

cases teeth, tonsils and adenoids should be eradicated and deformities of the nose interfering with the normal airway corrected. While gross abnormalities requiring surgical intervention will often be present many cases will be met with in which no abnormality is evident. In these the prognosis is bad but the patient's general health should be maintained at the highest possible level and every effort be made to safeguard him against catarrhal infections of the nose and throat. The patency of the Eustachian tubes is of the utmost importance and obstruction of them leads to a rapid loss of hearing and to changes in the middle ear which soon become permanent. The condition of the Eustachian tubes is ascertained by

FIG 1—Eustachian catheter

cases the ear affection occurs some months or years after an acute otitis media.

Starting at any age there is a history of increasing deafness in one or both ears usually tinnitus and frequently a blocked feeling in the affected ear. The variations from the normal seen on inspection of the drums over a series of cases are numerous but in any one patient little alteration may be visible. Unfortunately the condition of the membrana tympani has no direct relation to the degree of deafness. The most constant alteration in the drumhead is an increase of its normal concavity usually called retraction. The cone of light is distorted the long process of the malleus is drawn upwards and backwards and the

inflation with a catheter or by Valsalva's method. The latter is a simple procedure and should be tried first. Viewing the drumhead through a Siegle's speculum instruct the patient to close the anterior nares by pinching

FIG 2—Auscultation tube

short process projects conspicuously into the meatus. The outer surface of the drum is dull instead of shiny, whiter in colour and irregular in texture. In some cases this latter change is due to patchy thickening of the tissues of the drum and in others there are areas of atrophy. Viewed with a Siegle's speculum these irregularities are more evident and it will be found that the mobility of the drum is altered as a whole and often is not uniform over its extent. General retraction produces a lax and very mobile drum; atrophic areas move freely while the remainder is stationary. Not infrequently adhesions form between the drum and the inner tympanic wall and in these cases portions of the membrane are fixed and slight variations of air pressure produce no movement.

### PREVENTIVE MEASURES

Every case of chronic catarrhal otitis media must be thoroughly investigated with a view to determining the aetiology and giving treatment likely to prevent rapid increase of the deafness. Infection of the nasal accessory

FIG 3—Poltizer bag

sinuses, teeth, tonsils and adenoids should be eradicated and deformities of the nose interfering with the normal airway corrected. While gross abnormalities requiring surgical intervention will often be present many cases will be met with in which no abnormality is evident. In these the prognosis is bad but the patient's general health should be maintained at the highest possible level and every effort be made to safeguard him against catarrhal infections of the nose and throat. The patency of the Eustachian tubes is of the utmost importance and obstruction of them leads to a rapid loss of hearing and to changes in the middle ear which soon become permanent. The condition of the Eustachian tubes is ascertained by

### EUSTACHIAN CATHETERIZATION

This is a means of determining the degree of freedom with which air can enter the middle ear via the Eustachian tube in cases where Valsalva's test is negative or doubtful and as a method of treatment for Eustachian obstruction. The requirements are a local anaesthetic (a solution containing 5 per cent cocaine hydrochloride and 1 per cent ephedrine), a nasal atomizer, a malleable cotton wool applicator, cotton wool, a Eustachian catheter, a Politzer bag and an auscultation tube.

First spray the nose with some of the local anaesthetic mixture in the atomizer. This makes the subsequent manipulations less painful and facilitates the passage of the catheter by shrinking the nasal mucosa. After four

or five minutes paint the orifice of the Eustachian tube and adjacent area of the lateral wall of the nasopharynx with more of the local anaesthetic. A brush is made for this purpose by twisting a small piece of cotton-wool firmly on one end of the applicator and bending the latter into a shape resembling a Eustachian catheter. A six-inch length of thin copper wire flattened at one end to hold the wool makes an excellent applicator. Applied in this manner the anaesthetic diminishes sensibility of the nose and nasopharynx still more, and at the same time, by its local vasoconstrictor effect, tends to open the orifice of the Eustachian tube.

Choose a catheter of suitable size—Nos 2 and 3 are the most serviceable, make certain that its lumen is clear, by a preliminary blowing through with the Politzer bag, and that the attachment on the latter fits the catheter easily and securely, sterilize, and introduce. The introduction is made by gently pushing the catheter along the inferior meatus of the nose, the distal end being in contact with the floor until it glides over the upper surface of the posterior wall and the convexity of the curve touches the posterior wall of the nasopharynx. The point is then rotated outwards into a horizontal position, where it meets the lateral wall immediately posterior to the Eustachian cushion. Keeping the proximal part of the catheter on the floor of the nose, withdraw it slowly, and the point will be felt to pass over the Eustachian cushion. In this position rotate the point of the catheter upwards and outwards, and it will come in contact with the orifice of the tube. The amount of curve on the catheter has to be adjusted to the width of the nasopharynx. If, after touching the posterior wall of the nasopharynx, the catheter cannot be rotated into a horizontal position, the curve is too large and must be lessened. If, on the other hand, the lateral wall cannot be felt, the curve is too short. Having placed the catheter in position—a manipulation that must be performed with the utmost gentleness—steady it with the thumb and index finger of the left hand, resting the remaining fingers on the patient's nose. One end of the auscultation tube is placed in the operator's ear, and the other the patient holds firmly in his ear on the side being inflated. Instruct the patient to breathe quietly through the mouth, attach the Politzer bag to the catheter, and gently blow. If the Eustachian tube is patent air will be heard to enter the tube with each inflation, and the loudness and pitch will vary with the diameter of the tube and the force with which air is blown in. When obstruction is complete no air entry is audible, and a blockage removed by inflation is heard as a sudden 'pop,' which usually causes the patient to jump. In most cases in which the lumen of the tube is unobstructed the patient is conscious of the pressure of air on the inner surface of the drum. Complete obstruction, unrelieved by inflation, is treated by the passage of bougies.

The above method of politzerization should be employed to relieve Eustachian obstruction that persists after an acute coryza, and in the treatment of those cases of chronic catarrhal otitis media in which the lumen of the tube is unduly narrow and is occluded from time to time. The frequency with which the process has to be repeated depends upon the response. This is estimated from the state of the hearing and the readiness with which an obstructed tube can be relieved after the lapse of one or more weeks. Between treatments many cases derive much benefit from an inhalation of menthol each night.

In spite of every attention there is often a steady increase in deafness to a degree that necessitates the employment of a suitable aid to hearing or instruction in lip-reading.

### Chronic Suppurative Otitis Media

In this condition, for weeks, months, or years there is a continuous or intermittent discharge of pus from the middle ear unassociated with pain or pyrexia, with a perforation of the tympanic membrane and some degree of deafness. The initial infection is a specific acute suppurative otitis media which for some reason has not resolved. A consideration of the factors likely to lead to chronicity is the first step towards determining the correct line of treatment. These factors may be classified under three main headings.

1 *Mastoiditis*—Inadequate drainage in acute suppurative otitis media leads to adhesions in the middle ear, persistence of infection, and not infrequently its spread to the mastoid antrum and cells. The so called chronic suppurative otitis media is then associated with a chronic mastoiditis, and must be treated as such. Mastoid infection is to be suspected as the cause of the chronic otorrhoea in cases where the perforation is in the attic region, where polypi persistently re-form in spite of cholesteatoma removal and cleansing, and when flakes of cholesteatoma are present in the discharge. An acute suppurative otitis media continuing to discharge for more than four to six weeks in the absence of an obvious cause should be drained by mastoidectomy.

2 *Poor Hygiene*—This leads to chronic suppurative through mixed infection and as a result of a lack of resistance on the part of the patient. Proper cleansing, good food, and improved environment will terminate the condition in many suppurating ears that are apparently becoming chronic.

3 *Infection via the Eustachian Tube*—This is the pathway by which the acute infection reaches the middle ear, and not infrequently it is the path by which the suppurative process is kept alight from a focus of infection adjacent to the nasopharynx. Strictly speaking, no case of otorrhoea should be labelled chronic suppurative otitis media while gross infection is present in the teeth, tonsils, adenoids, or nasal accessory sinuses. The middle ear is reinfected in a manner comparable to that occurring in mastoiditis, and it is the source of the infection that must first be treated.

Having excluded cases that can be classified under the above three headings, there remain those in which suppurative otitis appears to be limited to the middle ear cleft, and these may be designated uncomplicated chronic suppurative otitis media. No one method of treatment is satisfactory for every case. The most suitable therapeutic measures are indicated by certain individual characteristics.

### Large Perforations

Where the whole or a large portion of the tympanic membrane has been destroyed, the mucous membrane is normally moist, which lines the middle ear is exposed, and is readily irritated by foreign particles gaining access via the external meatus. The natural response is an excess of mucus, which is discharged into the outer ear. If the Eustachian tube is patent an acute coryza will largely produce a profuse discharge. The correct treatment for such an ear is to provide adequate protection, and a convenient method is to keep the external auditory meatus well greased with a mild antiseptic ointment—for example, ung. hydrarg., oxid. flav. 1 per cent. The patient must be warned against allowing water to enter the outer ear, and should be persuaded to co-operate in constantly attending to the necessary protection. The hearing in the ear should be

often quite good and measures employed to dry up the middle ear destroy the mucous membrane and greatly increase the deafness.

#### Small Perforations

A tiny hole in the drum hinders drainage and prevents any treatment being applied directly to the middle ear. In dealing with the condition therefore first enlarge the perforation with a myringotome; this can be done under local anaesthesia. Six to eight drops of Bonnin's fluid (equal parts of phenol menthol and cocaine hydrochloride) introduced into the meatus after it has been thoroughly cleansed will produce complete anaesthesia in from ten to fifteen minutes. Subsequent treatment consists in daily cleansing with peroxide drops followed by syringing with boric lotion and the application of spirit drops. If simple cleansing fails to terminate the suppurative condition zinc ionization will probably do so.

#### Otitis Externa

This has been dealt with in a separate article. (See April 30 p. 988)

#### Granulations and Polypi

When present these must be removed. Small collections of granulation tissue are best destroyed by touching the surface with solid silver nitrate having first anaesthetized the area by applying 10 per cent cocaine hydrochloride for ten minutes. A convenient way of applying the silver nitrate is by fusing a small bead on to one end of a copper wire probe. Larger collections should be removed with a small scoop or aural curette after anaesthetizing with Bonnin's fluid. Apply a few drops of adrenaline 1 in 1000 to stop the bleeding then cauterize the area with silver nitrate.

#### Polypi

The main mass is removed with an aural snare. If the meatus is not obstructed to a degree that prevents the introduction of a local anaesthetic Bonnin's fluid will suffice but many cases will require a general anaesthetic. The snare is introduced over the polypus and slid down to its base which is then cut through. On no account must a polypus be dragged away from its attachment which may be to the inner tympanic wall. Bleeding is controlled by adrenaline and packing. Any pieces of the polypus remaining after the use of the snare are removed with a curette and by cauterization. After treatment entails regular cleansing and frequent inspection so that any recurrence can be immediately dealt with by the further application of caustic.

#### Marginal Perforations

These and the presence of polypi and granulations usually indicate infection of bone. The carious area is frequently quite small and can often be eradicated through the meatus. As mentioned above the base of a polypus should be scraped with a curette or be cauterized. Marginal perforations often continue to discharge because of the existence of caries in the tympanic ring where it forms one edge of the perforation. Removal of the diseased area with a small sharp scoop and subsequent cleansing will usually terminate the otorrhoea.

## INTERFERENCE WITH WIRELESS RECEPTION BY ELECTRO-MEDICAL APPARATUS

At the suggestion of the Postmaster General the Minister of Health has issued a circular letter to local authorities (No. 1693) enclosing a memorandum on the prevention of interference with radio reception from certain types of electro-medical apparatus. A leading article on this subject appeared in the *British Medical Journal* of April 9 1938 p. 786. The memorandum was prepared by the Radio Branch of the General Post Office and its purport has already been brought to the notice of the principal voluntary hospitals in this country through the British Hospitals Association in the issue of *The Hospital* for September 1937. The memorandum is primarily concerned with certain types of diathermy installations working on medium waves short waves and ultra short waves.

#### Electrical Screening of Rooms

Radio receivers situated at up to one mile or more from the electro-medical apparatus may be affected so that a single apparatus may affect a very large number of receivers. The radio services which may be affected are not only the BBC broadcast and television transmissions on long medium or ultra short waves but also Government service Air Force civil aircraft police shipping and other commercial services in some of which the safety of life on land at sea and in the air may be involved.

The interference may reach a radio receiver by two means—either by conduction from the source along the electric supply mains from which it is eventually radiated to the aerial or by radiation from the source directly to the radio receiving aerial. The former method of propagation is known as mains borne the latter as direct radiation. Mains borne interference can be suppressed by connecting in the mains supply to the diathermy apparatus a suitable filter consisting of condensers and/or radio frequency inductors (chokes). Directly radiated interference can only be suppressed by enclosing in an electrical screen or Faraday cage not only the apparatus but also the patient and the operator. This is not practicable in the case of the mobile ward unit but may be applied to the considerably more common case in which the bulk of the treatment is given in one room set apart for the purpose. This latter case is the one which in practice gives rise to the large majority of complaints of interference with radio reception.

It is obviously undesirable to enclose the apparatus patient and operator in a closely fitting screen and the method of screening which have been developed by the GPO Radio Branch rely on fitting the screening material to the surfaces which enclose the room in which treatment is given. Two methods in particular have been developed one primarily for dealing with an existing room the other for application to a building which is in course of erection. In the former case metallized paper is applied to the walls doors and ceiling of the room above the plaster the floor being covered with either heavy gauge metallized paper or else with quarter inch wire netting. The floor screening material is covered by linoleum or other floor covering. The recommended type of metallized paper consists of aluminium foil (not sprayed aluminium or aluminium paint) supported on a paper backing. The windows are covered with wire netting.

It is desirable that provision should be made in any new hospitals or extensions to existing hospital buildings in which apparatus of this kind is likely to be used for the inclusion of screened rooms of the type outlined in the memorandum. The Radio Branch of the General Post Office is prepared to advise on any problems arising in the provision of screened rooms for future installations as well as on the prevention of interference which may be found to be caused by existing plant.

Pending further consideration of the important question discussed in our leading article regarding the suitability of certain wave bands which might be reserved for the users of electro-medical apparatus the Secretary of the British Medical Association would like to have as much information as possible from members possessing expert knowledge.

On the occasion of the appearance of the hundredth volume of the *Klinische Monatsblätter für Augenheilkunde* the publisher Ferdinand Enke of Stuttgart has founded a Theodor Axenfeld Prize for the best paper published in that journal during the past two years.

## CANCER OF THE CERVIX UTERI

## GROUPING OF CLINICAL STAGES

In the autumn of last year<sup>1</sup> we reviewed a pamphlet issued by the League of Nations Health Organization on the results of radiotherapy in cancer of the uterine cervix. This has now been followed by the publication of an *Atlas illustrating the Division of Cancer of the Uterine Cervix into Four Stages*—which has been prepared by Dr J Heyman and Dr M Strandquist of Stockholm. It consists of a series of thirty-eight diagrams in which the extent of neoplastic spread is clearly indicated, while facing each page of diagrams is the descriptive text in English, French, and German. The compilers have taken special care to ensure an exact correspondence of meaning in the terms used in the three languages, a circumstance which greatly adds to the value of the book.

## Revised Definitions

In view of the experience gained since the four grades or stages were first defined in 1929, it has been found desirable to make some modifications in the various definitions, and these are included in the present work. Under the old rules of classification it often occurred that there were marked discrepancies in the reports from different centres owing to lack of agreement in the exact interpretation of the directions regarding grading.

The main causes of difficulty have arisen in differentiating between the second and third groups in those cases where the degree of parametric invasion was the deciding factor. In the definitions as originally given the extent of parametric invasion was based mainly upon the degree of uterine fixation. In the revised definitions the distinction between the second and third stages is based entirely on what can be ascertained by rectal and vaginal examination regarding the relationship between the growth and the pelvic wall. For this purpose the "pelvic wall" is understood to include the pelvic bone, muscles, fasciae, blood vessels, and lymphatic glands—that is, the pelvic wall as appreciated by the finger of the examiner. Considerable simplification has been made in those definitions where the grouping depends upon the vaginal extent of the growth. The definitions of 1929 were drawn up on an anatomical basis, and, as regards Stage IV, in order to counteract a generally accepted although erroneous idea that all "hopeless" cases should be referred to that stage. It often happens that cases which anatomically belong to Stage III are nevertheless "hopeless" owing to the patient's general condition, and conversely a certain number of cases which under the 1929 definitions belong to Stage IV are not hopeless.

## Accuracy and Uniformity of Grading

For these reasons it is suggested that Stage IV should consist only of those cases in which there is involvement of the bladder and rectum or where extension outside the true pelvis has occurred. It is admitted that this revision of definitions will reduce the comparability between results obtained at the same clinic before and after 1938, but this is regarded as of minor importance in view of the greater accuracy and uniformity of grading, while the results obtained in different clinics for the same year will be strictly comparable. The allocation of any

case to its proper grade should be governed by the conditions found on inspection, on bimanual examination—vaginal or rectal—and on cystoscopy when there is any question of the bladder being involved. In endeavouring to discriminate between an advanced example of a particular stage and an early example of a succeeding stage, it should be a general rule to allot cases to the prognostically more favourable earlier stage, so as not to raise unduly the proportion of favourable results in the less advanced grades.

The revised definitions as given in the present *Atlas* are as follows:

*Stage I*—The carcinoma is strictly limited to the cervix.

*Stage II*—(a) The carcinoma infiltrates the parametrium on one or both sides, but has not invaded the pelvic wall.

(b) The carcinoma infiltrates the vagina but does not involve its lower third.

(c) Endocervical carcinoma which has spread to the corpus.

*Stage III*—(a) The carcinomatous infiltration of the parametrium has invaded the pelvic wall on one or both sides. On rectal examination no cancer-free space is found between the tumour and the pelvic wall.

(b) The carcinoma involves the lower third of the vagina.

(c) Isolated carcinomatous metastases are palpable on the pelvic wall (irrespective of the extent of the primary cervical growth).

*Stage IV*—(a) The carcinoma involves the bladder as determined by cystoscopic examination or by the presence of a vesico-vaginal fistula.

(b) The carcinoma involves the rectum.

(c) The carcinoma has spread outside the true pelvis (below the vaginal inlet, above the pelvic brim, distant metastases).

## General Rules to be Observed

1 When allocating a case to a stage nothing but facts revealed by examination should be taken into account.

2 The stage of each case should be decided at examination prior to treatment, and this classification should remain. The classification may be postponed quite exceptionally and the reasons stated.

3 When it is doubtful to which stage a given case is to be allocated the earlier stage should be chosen.

4 The fact that a single case presents two or more of the conditions which characterize a particular stage does not affect the grading.

The *Atlas* will be found of the greatest value in all clinics where research work is undertaken, and its small size adds to its convenience for reference. We are asked to state that institutions wishing to collaborate in the international standardization of reports should communicate with Dr J Heyman, Radiumhemmet, Stockholm, from whom all necessary information can be obtained. Copies of the *Atlas* are procurable from the Publications Service of the League of Nations, Geneva.

<sup>1</sup> *British Medical Journal* October 16 1937 p 755. The original definitions of the four grades are reported in this annotation.

At the annual meeting of the Milbank Memorial Fund held in New York City on March 29, it was announced that nicotinic acid is now being artificially produced at so low a cost as to make it additionally useful in treating the poor man's disease. In the United States of America nearly half a million people suffer from pellagra, of whom 3500 die from the disease every year. It may be recalled that one of the pioneers to discover the cause of pellagra was Cesare Lombroso (1836-1909). An impetuous and versatile genius—at the age of 12 he published two small works on Roman architecture—he is chiefly known as the founder of the science of criminal anthropology. Fifty years ago, in his book *L'Uomo del Genio* (*The Man of Genius*) he advanced the theory that genius is essentially an epileptiform neurosis.

## Reports of Societies

### NON MALIGNANT OESOPHAGEAL STENOSIS

At the meeting of the Section of Surgery of the Royal Society of Medicine on May 4 Professor GREY TURNER delivered his address from the chair taking as his subject non malignant stenosis of the oesophagus.

Professor Grey Turner said that the practical importance of simple stenosis of the oesophagus was undoubted and during the last two or three years he had seen many examples of the condition. He had long been impressed with the difficulties in the management of some of these cases. In 1911 he saw a child aged 3 who was constantly eating and regurgitating whatever was put before him. Dilatation was carried out through the oesophagoscope and afterwards by bougies which the patient learned to pass. Now after twenty five years he remained well and with full swallowing capacity.

It had been traditional now for a long time to expect that these cases could be successfully dilated through the oesophagoscope and perhaps cured but this method was not always successful and was often attended with great risk.

A lad of 19 after dilatation of such a stricture became very ill and appeared to be dying of mediastinitis, an empyema also developed. He slowly recovered though gastrostomy had had to be undertaken to save his life. Exploration of the oesophagus from the abdomen showed that the stricture extended much too far up for any plastic operation and bougies could not be passed by the retrograde method. It seemed that a new oesophagus would have to be made but he persevered with bougies by the mouth although only the time the instrument could pass through the stricture in the first instance. The boy eventually passed the largest bougie and now four years later he was perfectly well although about once every two months he passed the bougie as a sort of insurance.

After describing two other similar cases Professor Grey Turner went on to say that sometimes this method could not be employed. In one such case he had exposed the oesophagus from the abdomen and had carried out cardioplasty with complete success. Twelve years afterwards the patient a boy remained fit and well and he had never had a bougie passed since the operation. The method of anastomosis was not often indicated but he had employed it in seven cases and in one especially in which the operation was conducted through the chest the result had been most satisfactory though unfortunately the patient was killed two and a half years later in a motor-car accident. A necropsy showed the almost impossible condition of the stricture from the point of view of any other treatment, and the effectiveness of the anastomosis.

#### Ætiology

The causation of fibrous stricture was usually quite obvious, it generally resulted from the swallowing of corrosive fluids. Nevertheless there were other causes such as local and general infections like typhoid and some of the other acute infective fevers. Though he had not seen the type of extreme destruction by digestion which Pringle and Teacher described he had very often noticed milder destructive changes in the oesophagus almost certainly due to regurgitation of very acid or perhaps toxic stomach contents in patients who had long been extremely ill. This condition must occur in many patients who recovered and he believed that a lesion thus set up might occasionally lead to benign stenosis.

Brown Kelly of Glasgow had shown that a secondary fibrosing condition might start in association with some

mild congenital defect. The diagnosis not as to the cause but as to the actual condition present was usually obvious but it was necessary to realize that there were cases in which difficulty occurred. In this connection he recalled a case which came under his observation before the diagnostic methods now employed were available. Owing to the extraordinary improvement after gastrostomy in this patient dilatation was carried out and with some success. Subsequent post mortem examination showed a well-developed growth. Such a sequence of events might be thought well nigh impossible in the old days but recent experience showed that there were still avenues of error.

#### Prevention of Stenosis

The prevention of stenosis in the presence of such conditions as were almost invariably followed by its development was important. Salzer advised the passage of instruments in the very early days although the traditional view was that it was better to defer any such treatment until four or six weeks after the accident. He had himself seen a perforation of the oesophagus by a bougie on the twenty-sixth day after the swallowing of carbolic acid. He would hesitate to attempt any dilatation until the stage at which fibrosis had become well developed. As to the ultimate condition of patients who had suffered from cicatricial stenosis of the oesophagus many—possibly the majority—might be permanently cured by persistent treatment but it must be realized that there was probably a residue of cases in which the tendency to recurrence persisted for many years and perhaps throughout life. One of his patients who first showed signs of such a lesion when aged 7 had been treated with great success and at 16 was able to swallow normal food. Of late years however she had neglected the regular use of the bougie and now had some pain behind the sternum and a skiagram showed that there was a well defined hold up at the lower end of the oesophagus. It was Trousseau the French clinician who said that a patient using the oesophageal bougie would die of the instrument sooner or later and it must be recognized of course that there was danger in this treatment. Nevertheless experience led him to conclude that the careful self passage of bougies blind though it might be was certainly not attended with more danger than the rapid dilatation carried out through the oesophagoscope. It was undoubtedly a very dangerous practice to pass a blind bougie under an anæsthetic.

#### Other Methods of Treatment

Other methods were available of the value of which he was not unmindful. The swallowed string usually associated with the name of Plummer and so successfully employed by him had a great field of usefulness but there were many cases in which it would not avail and there were others in which the patient tolerated this method badly. In all difficult cases it ought to be tried before other measures were contemplated or rather when other and simpler methods had been tried and had failed. He had personally not had any success with the retrograde passage of bougies through a gastrostomy but others had had some success and it was a method that at least could easily be tried. Cutting through the stricture with a string saw was a violation of surgical principles which made no appeal to him. His experience in oesophagectomy led him unhesitatingly to condemn attempts at excision of a simple stricture with end to end anastomosis.

In cases that had defeated the various methods mentioned there was always the possibility of making a new oesophagus and to this end a vast amount of ingenuity had been exercised with an encouraging degree of success. The late Professor Zaajer of Leiden had done much along these lines. A friend of his told him that he had seen no fewer than eleven patients in one hospital in Moscow all suffering from simple stricture of the oesophagus, the result of swallowing caustic fluids in suicidal

attempts, in each case the surgeon in charge was busy with the formation of a new oesophagus. Surely, one could scarcely imagine that such a wholesale resort to this procedure must be necessary, and he could not but feel that more and more effort should be exercised in an attempt to restore the natural path rather than to by-pass it by means of a surgical exploit of such magnitude with its attendant risks.

At the close of the address, which was illustrated with lantern slides, Mr SAMPSON HANDLEY proposed a vote of thanks to Professor Grey Turner for a communication which had embodied an extraordinary number of interesting clinical facts. The President, he said, had won many triumphs in a field where the difficulties were enormous and where only great knowledge and great determination could bring successful results.

At a meeting of the Devon and Exeter Medico-Chirurgical Society on April 28, with Dr ROBERT SCOTT, the president, in the chair, Dr W. A. ROBB read a brief paper on the necropsies carried out in two cases of sudden death, death was due in one case to pleural shock and in the other to rupture of an aortic aneurysm. Dr CHARLES SEWARD described a case of profound anaemia which seemed to be nutritional in origin.

## Local News

### ENGLAND AND WALES

#### Financial Position of Guy's

Two years ago Guy's Hospital made an appeal for half a million for rebuilding and essential re-equipment. So far about £200,000 has been received. This has enabled the dispensary to be reconstructed, a children's ward to be erected, the nurses' home to be enlarged, and the debt to be reduced by some £82,000. A new appeal is now being made for the balance of the half-million, and Lord Nuffield, the treasurer of the hospital, has offered to give £80,000 for a new nurses' home if this balance—actually £316,000—is subscribed by the public. This large sum is needed mainly for the purpose of rebuilding or replacing some of the eighteenth century parts of the hospital, the state of which has become perilous. Guy's is one of the most picturesque of the London hospitals, but the age of the building in parts is very apparent. What is now the surgical block is really the old hospital building, not much altered since its erection in 1725. Rebuilding has been deferred again and again, but the time has come when the question cannot longer be shelved. The hospital architect reports that the outer walls are beginning to sink, and the whole of the surgical work is threatened with serious curtailment, if not complete cessation, for a while. The whole of this block will have to be pulled down, though it is hoped to keep the original façade. At a luncheon in support of the appeal, held in the board room, attention was called to the cracks across the ceiling painting—a florid composition which represents Thomas Guy being wafted up to heaven on a cloud—which are due to the subsidence of the walls. It was stated to be not a question whether the hospital could continue to compete with changing conditions but whether its fabric could remain standing with safety for those who work or lie in it.

The £316,000 for which the appeal is now made is required principally for the rebuilding of the surgical block to provide 300 beds but additional accommodation for ward maids is necessary, and it is also hoped to complete the reduction of the debt by setting aside a

further £83,000. The present maintenance cost of Guy's is about £221,000 annually, the assured income is £69,000, and the balance of £152,000 has to be obtained from voluntary sources but has not in recent years been fully forthcoming, with the result that a debt of serious proportions has accumulated. The appeal, signed by Lord Goschen, president of the hospital, Lord Nuffield, treasurer, Sir Alfred Beit and Lord Ebbisham, chairman and vice-chairman of the Extension Fund Appeal Committee, and Captain Eric Waley, chairman of the Standing Appeal Committee, points out that although Guy's is a London hospital, it does not confine its work to the metropolis. The records show that over 42 per cent of its patients come from the rest of the British Isles. The doctors, dentists, and nurses from its school serve in every part of the Empire. Lord Nuffield, in commending the appeal, states that during his lengthening association with Guy's he has been deeply impressed with the skilful way in which the hospital has been run on an economic basis, while ensuring the maximum of care and attention for its patients. "It is this fact which has influenced me so greatly in my decision to make a promise of £80,000 contingent on the balance of the amount appealed for being raised. This statement is made in no spirit of self-advertisement, but purely as an assurance of my knowledge of, and implicit faith in, Guy's. I therefore feel that I can, with a clear conscience, ask others to give, and look forward with confidence to the Governors being in a position to call upon me for this amount."

#### The Tavistock Clinic

The annual report of the Tavistock Clinic (formerly known as the Institute of Medical Psychology) states that much of the nation's problem of mental ill health could be solved if only there were more doctors trained to deal with such cases. Hence the Council has come to regard educational work among medical men and women as its most important national contribution, though the resources of the clinic are so small that only twelve a year can be trained. Some time ago the Council acquired a large site on which to erect an adequate medical school, besides a hospital and out-patient department. Lack of funds has held up the work, and meanwhile mentally sick people in all parts of the British Isles are drifting nearer to the "borderline" because there is no one to help them. During the year 1937, in the clinic's restricted premises in Malet Place, Bloomsbury, more than 23,000 hours were spent by the medical staff on giving individual treatment to specially urgent cases. The Tavistock Clinic was founded in 1920, and has grown from very modest beginnings to its present position in the medical world, owing to the enormous demand for treatment of a type of illness by psychological methods for which no out-patient facilities existed in this country before that date. Its work aims at the study, alleviation, cure, and prevention of those disorders of mind which are not classed as insanity or mental deficiency, but which nevertheless cause profound and widespread suffering and economic disability in the community. These comprise hysteria, morbid fears and obsessions, sexual abnormalities, as well as behaviour disorders in children, such as lying, stealing, truancy, and the like. Those of modest means who are in need of such treatment receive as part of their preliminary consultation a thorough physical examination, and both then and during treatment are seen by appointment just as if they were attending a specialist in private. In addition to the work of regular treatment, the medical staff give consultations to numerous patients whose doctors seek special advice.

#### Community Centres and Public Health

On May 5, at the London School of Hygiene, Professor Ernest Barker gave a Chadwick Public Lecture on Community Centres in Relation to Public Health. He pointed out that such centres and the associations behind them

in primarily on new municipal housing estates, but they were spreading to private housing estates, and even to the old and established quarters of our towns. Their aim was physical and general recreation, and they included juveniles as well as adults. They were a new and important development of the general English system of voluntary association; they were also a new and important development in the history of the promotion of public health. Their activities included gardening and various forms of physical recreation; they marked a general attempt to build a good and healthy life by common effort in harmony with the environment. They formed a natural purchase which the State could use in its efforts to encourage positive physical fitness. There were three ways in which the community centre might contribute to the cause of public health. In the first place the local authority might establish there some of its statutory medical services—for example, for maternity care and for infant welfare. Secondly the National Fitness Council might provide the community centre, from the funds at its disposal with equipment (such as gymnasia and swimming baths) enabling its members to carry their aim of physical recreation to greater lengths and so develop health and happiness more successfully. Thirdly it was possible (as had already been attempted at the Peckham Pioneer Health Centre) that a community centre might include some form of regular medical overhaul and health supervision among its activities. The Peckham Centre was indeed *suo generis* medicine and a body of doctors there came first and a community developed on that basis. With the community centre proper the reverse would be the case: the community would come first organized in an association and it might then arrange with the public health medical officers or by other means for some system of overhaul and supervision. In any case this development lay in the future: the Peckham Centre as yet was on the whole unique though at least one other centre had arranged for the provision of some medical facilities. Generally Professor Barker concluded the community centre apart from these specific methods rendered a general service to the cause of public health by being a voluntary organization whose members were fully occupied with activities (mental as well as physical) which used and developed body and mind simultaneously.

## SCOTLAND

### Insanity in Scotland

The report for 1937 of the General Board of Control for Scotland shows that on January 1 last there were 19,687 insane persons known to the Board exclusive of insane persons maintained at home. The number of certified patients admitted to institutions during 1937 was 2,735 or 171 more than in the previous year and the number of patients discharged included 579 recovered and 289 unrecovered. 1,449 patients died. Referring to the results of treatment of general paralysis by the induction of malaria the report states that in many patients the disease had been arrested and some were able to return to their occupations while the mortality in Scottish asylums from this and other syphilitic affections of the brain had decreased from 201 deaths in 1921 to 67 in 1936. The administration of this treatment in general hospitals in the early stages of disease had further diminished the number of beds required for general paralytics in lunatic asylums. Treatment of dementia praecox by injections of insulin or cardiazol had been tried, but although results were encouraging it was too early to arrive at definite conclusions. The report also mentions the increasing difficulty that had been encountered in obtaining female nurses for asylum nursing and states that in six institutions a forty-eight-hour week is already in operation while it had been

decided to introduce these shorter hours in another six institutions. The number of patients boarded out under private care at January 1 1938 was 29,400 of whom 1,144 were lunatics and 1,510 mental defectives. Reference is also made to the continued insufficiency of institutional accommodation for mental defectives and the dangers resulting from lack of regular and systematized training for juvenile defectives. It is false economy the report states on the part of local authorities to allow children under 16 years to go without training in habits and occupation for untrained and poorly supervised defectives especially those living under city conditions run a grave risk of getting into trouble. The cost of rate aided lunatics for the year was £971,211 and of rate aided mental defectives £302,288. The total cost of local and imperial funds amounted therefore to £1,273,499 of which £26,948 was recovered from private sources.

### Glasgow University

At the annual meeting on April 27 of Glasgow University General Council Sir Hector J. W. Hetherington, the Principal, spoke on the needs of the university. In the last three years he university had accumulated a debt on running expenditure of about £24,000 for which he had no reserves although some relief might be forthcoming from the Scottish Education Fund. A commission appointed by the Secretary of State for Scotland had been investigating the financial position of the four Scottish universities although its report had not yet been issued. The university was also in urgent need of capital—for example a great new chemistry laboratory was being erected in University Avenue at a cost of £16,000 and of that money they had in hand £15,000 so that a further £50,000 was necessary. The Government was paying £3 to the university's £1 for the cost of a new reading room which would be the central feature in the development of the Hillhead house site at a cost of £20,000 but the university was £1,000 short on this scheme. An offer of £10,000 on a 50 per cent basis had also been received from the Physical Training Grants Committee towards the cost of quarters for the physical welfare of the men students on the site of the present gymnasium; the university's contribution for this had still to be raised.

### Health of Glasgow Children

The report for 1936-37 on the medical inspection and treatment of school children issued by the education health service of the Public Health Department of Glasgow records a general improvement in the health of children in that city. It is stated that the average heights and weights are the highest since these reports were first instituted twenty-eight years ago. Gross and serious pulmonary conditions which were frequently encountered during the early years of medical inspection are now rapidly disappearing. Many children however receive treatment for pulmonary affections of a minor nature and this may be attributed to the growing appreciation on the part of parents that early treatment is followed by more complete and more rapid restoration to a normal state of health. The report states that there has been considerable development in the provision of new open air schools and of open air classrooms attached to existing schools. Whereas in 1930 there were thirty open air schools and nine old buildings with open air classrooms as extensions the respective numbers for the year under review were fifty-two and twenty-four. It is estimated that more than 25 per cent of the school population is now housed in open air schools and classrooms. The daily milk ration inaugurated early in 1935 is another factor contributing to the improved health of the children. Bottles containing one third of a pint of high grade pasteurized milk are supplied to necessitous children free of cost and to others at a charge of a halfpenny per bottle. More than twenty million bottles of milk were distributed during the year.

## Correspondence

### The Heart in Gall-bladder Disease

SIR—I was much interested in Dr S M Laird's paper (*Journal* April 23, p 884), particularly from the statistical point of view. There are certain debatable points.

The number of cases—namely, sixty-four—examined by Dr Laird appears to be much too limited. If one realizes that it is obviously necessary to consider different age groups separately, this number becomes even smaller (five eleven seventeen, and four in Dr Laird's paper). In view of the fact that the incidence of heart lesions is comparatively high after middle age it seems reasonable to investigate at first only younger patients say, between 30 and 35 or 30 and 40 years of age. If such investigations should prove definitely either positive association or no association at all between heart and gall-bladder disease for the age group considered, one could afterwards investigate other age groups if necessary.

This criticism would equally apply to the controls of Schwartz and Herman from the point of view of the small number of cases. The choice of controls, in which they exclude cardiac cases *per se*, is also, in my opinion, a debatable point. Would it not be wiser to apply the method very often used in statistics to this particular investigation—that is, *not* to choose a certain number of gall-bladder cases and an equal number of non-gall-bladder cases but to examine *all* cases in a certain age group admitted to hospital within a certain time and to divide them into gall-bladder and non-gall-bladder cases subdivide them again into cardiac and non-cardiac cases and then to investigate the "association" between gall bladder and heart disease in each group and subgroup? If this method is used the cases with normal gall-bladders would probably be much more numerous than those with disease of the gall-bladder and the difficult question as to which cases should be excluded from the control series would not arise—I am, etc.,

Jewish Herzl Moser Hospital,  
Leeds May 5

ALFRED MODEL

### The Planning of Maternity Hospitals

SIR—In the annotation in your issue of April 30 (p 955) you quote the recommendation of the Departmental Committee on Maternal Mortality and Morbidity that "new maternity accommodation should, when practicable, be associated with general hospitals, but you add "it is now however generally accepted that this recommendation is not in accordance with the lessons of experience."

The experience of the members of the North-Western Branch of the Medical Superintendents Society has not led them to this conclusion and their experience of large maternity departments is not negligible since 2 to 3 per cent of the births of England and Wales take place in hospitals for which they are responsible. They have recently recommended that accommodation for maternity cases should be provided by municipalities in departments of general hospitals rather than in special hospitals, and they give a number of reasons for this recommendation. The municipal hospital must provide a complete service, and cannot choose and select cases in the same way as a voluntary organization. Hence provision must be made for all sorts of difficult and awkward cases that do not fit

into the neat classification scheme of the ordinary voluntary hospital. It is much easier to deal with these cases when in the background are the resources of a general hospital.

Pregnancy may be complicated by general disease or injury, by venereal disease, by tuberculosis or other infectious disease. It is greatly to the advantage of patients so affected if there is in the hospital a staff specialized in all branches of medicine and surgery to give advice on treatment. The services of the special departments of the hospital, such as the x-ray department or the physiotherapy department, can be used for diagnosis and treatment. A general hospital will have a complete pathological department. The post-mortem work can be done by someone who is not in the actual practice of midwifery. The paediatric physician on the staff will be able to advise on diseases of the new-born. Cases of puerperal sepsis can be nursed in a ward attached to a medical unit attended by nurses who are not doing midwifery, yet they remain under the supervision of the maternity staff. Cases of diseases and complications of the puerperium can be admitted to general wards under the care of the maternity medical staff.

Gynaecology is very intimately associated with midwifery. In a general hospital the gynaecology wards together with the wards for abortion, will be under the same staff as the maternity unit. In the wards of a general hospital patients who are admitted suffering from some general disease such as pneumonia, cardiac disease, etc., are sometimes found to be pregnant. These patients are likely to benefit by the advice and treatment of an obstetrician. Lastly, in a general hospital there will be a medical and lay administrative staff to give help in all kinds of administrative matters—I am, etc.,

HENRY H. MACWILLIAM  
Chairman North Western Branch Medical  
Superintendents Society

Liverpool May 2

### Sulphanilamide and Pentothal Sodium

SIR—Since the recent increase in the use of sulphanilamide preparations, an anaesthetic risk has arisen which I have not yet seen mentioned in the medical press. It is well known that in certain individuals the simultaneous administration of sulphanilamide and drugs containing sulphur may cause sulphaemoglobinaemia. As the molecule of pentothal sodium contains a sulphur atom and the drug is usually given intravenously, it seems very probable that trouble may arise if it is given to a patient who is receiving sulphanilamide—I am, etc.,

London, NW 8 May 3

C. LANGTON HEWER

### Divinyl Ether Anaesthesia

SIR—General practitioners working at small hospitals need a good method of anaesthesia which can be applied safely and conveniently to a wide range of different cases. In many such hospitals a Boyle's apparatus is available. As sent out by the maker this apparatus usually has a bottle for chloroform and one for ether. Filling both bottles with ether is a common practice and has the advantages of safety and a high concentration of ether. Induction is not very rapid and large quantities of ether have their disadvantages. Since reading Dr V. Goldman's paper (*Journal* December 25 1937 p 16) I have used one part of divinyl ether to three of ethyl ether in the first bottle and ethyl ether alone in the second bottle. (The divinyl ether has been obtained from May and Baker under the trade name of *vinyl-ether*.)

I have given this mixture to twelve children for gonorrhoea and to seventeen adult patients of both sexes whose ages ranged up to 70 for procedures varying from appendicectomy to haemicolectomy. The premedication undertaken varied: two or three nervous patients had morphine grain 1.4 and hyoscine grain 1.150. At least three of the adults and most of the children had no atropine but most of the adults had 1.75 grain of atropine. In every case induction was smooth, quick and easy except for momentary cyanosis with mucous obstruction in one child who had had no premedication but gave no real anxiety. The mixture was demonstrably stronger and less irritating than ether but does not seem so strong as to be dangerous even in inexperienced hands.

I have so far turned on the ether bottle freely for upper abdominal operations but the relaxation even in patients who were not deeply under the influence of the ether has usually been excellent. A patient under gas and oxygen and divinyl ether-ethyl ether anaesthesia who would almost become conscious if given a few breaths of air may never be fit for abdominal surgery. As regards mouth and throat operations tracheal intubation has disadvantages and is not always easy for those who do it rarely. Divinyl ether (with gas oxygen or air) has to be used in prodigious quantities in a robust patient a practical alternative to these without chloroform is valuable. The mixture given continuously with gas and oxygen into the side of a mouth open for tonsillectomy maintains as easily as chloroform would anaesthesia of moderate depth.

Recovery after short but quite deep anaesthesia is disconcertingly rapid—an excellent thing when little post-operative pain or shock is expected. Where pain or shock was expected it appeared wise to order morphine before, during, or immediately after the operation. The post-operative stage is satisfactory: there has been practically no vomiting, no untoward symptoms have arisen and I think the elderly patients have coughed a good deal less than one would have expected after ethyl ether alone. In conclusion this mixture appears to me to possess such definite advantages that in spite of the high price of divinyl (approximately 3s. per ounce) it ought to receive a much wider trial than I can give it—I am etc.

Woodford Jubilee Hospital April 28

E. B. GROGONO

### "Gonococcus Antitoxin" for Gonorrhoea

SIR—In answer to the adverse critics on this subject in your recent correspondence columns may I refer again to my reply (March 26 p. 701) to the paper published by E. T. Burke, J. Gabe, A. H. Harkness, and A. J. King (March 19 p. 605) in which they recorded complete failure to obtain a single satisfactory result with gonococcus antitoxin.

In my last paragraph I wrote

"Upon analysis of twenty-five consecutive cases treated [with gonococcus antitoxin] in the latter part of last year the results are comparable to those already published by myself. As it is impossible to give full details of the protocols here I will gladly submit these records to the authors. They are not from my pen but are the routine observations written by my various medical colleagues in the venereal department at St. Thomas's Hospital."

May I add that the cases were carefully investigated and protosil or some allied substance was not used by way of adjuvant.

These authors did not accept this invitation nor before the publication of their article, either verbally or in writing,

did they ask for my observations or inform me of their experiences with the antitoxin (a new product still in the early stages of investigation). I extend the invitation to your correspondents Dr. W. Lester and Dr. N. Seddick Taylor to visit the venereal department at St. Thomas's Hospital and inspect the protocols for themselves. There the patients suffering from acute gonorrhoea are given antitoxin as a routine. May I repeat that this would not be done nor would I permit it were they obtaining no therapeutic benefit or experiencing the severe reactions described in such a high percentage by E. T. Burke and his co-workers.

At the moment the response of cases (the tenth series under observation) to antitoxin with sulphamidamide is being investigated. The possibility of such a combination was referred to by me in *St. Thomas's Hospital Reports* (1937 2 67) and more recently in the *Medical Annual* for 1938—I am etc.

### Insulin for Schizophrenia

SIR—In reply to Dr. B. H. Shaw's letter of your issue of May 7 (p. 1026) there are some points which might interest him in a paper I read before the Royal Medical Psychological Association (S.W. Division) a day or two ago. The subject was "A Variation of the Treatment by Insulin Shock" in which neither shock nor coma is produced. Insulin and histamine are used together in subtoxic doses the patient is in no way upset and the results so far are good. In this method there is no sudden spectacular return to normality but the return proceeds slowly and can be watched. If the patients react well they do not seem to slip back—I am etc.

### Origin of Cancer

SIR—In connexion with the interesting correspondence on the causation of cancer I would like to submit the following suggestion.

In his embryological development the individual reproduces the history of his race—that is in order to reproduce our kind a start has to be made from the beginning. In the mental sphere we find the same start *ab initio* whenever a major readjustment to circumstances is required. For instance grief is a condition not far removed from the infantile state and the same applies to many psychoses and psychoneuroses. Without a due sense of grief or other infantile regression complete recovery or readaptation is impossible and neurosis results.

The second principle concerns the nature of the tissues attacked by malignant disease. The body or that part of the psychosomatic unit which is exposed to the material environment may be said to possess two surfaces. The aerial surface comprises what is usually known as the outer surface with its intolings the skull sinuses, auditory meatus, etc. The aquatic surface on the other hand consists of the linings of the blood vessels, lymphatics, pericellular lymph spaces and the cell membranes. This separation into aerial and aquatic surfaces is not however quite perfect. The respiratory tract and the gastrointestinal canal for instance are purely aquatic surfaces in aquatic animals. In land animals on the other hand the lining membranes of these tracts are intermediate between the two types of

surface They are phylogenetically newer and therefore less adapted to their function than the older aquatic surfaces They are also moist surfaces exposed to both aerial and aquatic conditions and they have not had the chance of adaptation to their conditions that the outer aerial surface has had through constant exposure to the air In the case of the gastro-intestinal tract, bile ducts and canaliculi, etc., the constantly moist conditions preserve in them a tendency to retain their aquatic character whereas the presence of gases must create some tendency towards the establishment of an aerial form of surface That this transitional surface is a special surface is shown by the special types of epithelium with which it is covered

It is not surprising that these transitional tissues, subject to both an aquatic and aerial environment, should be burdened with an inherent instability If we may infer such an instability then readjustment must at times be necessary and as we have seen, where readjustments are required the repetition principle operates, the tissue reproduces itself in embryonic cells, and, since readjustment to such difficult conditions must be hard to achieve, the process continues, the affected organ forming as it were, a uterus in which the new tissue proliferates

Malignant disease would appear, then, to be an attempt on the part of an unstable transitional surface at readjustment in accordance with the repetition principle to external conditions which are not constant—I am, etc,

Exeter May 7 H WILFRED EDDISON, M D, D P M

SIR—There is such an amount of reasoning from analogy in the most interesting instructive, and valuable discussion on malignant disease in your correspondence columns that one might well be certain of the facts

Mr E G Fenton (*Journal* May 7, p 1024) states that the potential of a weight in a grandfather clock is greatest at the top Surely the potential is the same all the way down else the clock's speed must vary Is Mr Fenton's 'developmental energy' not our old friend and mystical power the force *hypermecanique* that vital force which, neither physical nor chemical in its nature, was held to be active in living organisms only? This doctrine was finally overthrown It slips in now and then Whether it explains anything is a point and the *Encyclopaedia Britannica* says It would, it is true appear as if in our day, after the lapse of half a century, mystical tendencies were again disposed to crop up in the investigation of life This makes it all the more important to get the facts right Surely the weight is at the same 'potential' all the way down—I am, etc,

Crews May 7

W L ENGLISH

SIR—I should like to put forward the following hypothesis is going some way to explain the relation of the two causes of cancer—virus and 'chronic irritation' If the intracellular virus which is fundamentally responsible were only able to penetrate the cell membrane and successfully invade the cell during a particular phase of cell division or mitosis in which the resistance of the cell membrane was weakened, then the operation of some factor which prolonged this phase might be a necessary preliminary to the formation of a cancer cell Such factors would be (1) most chronic irritants causing repeated division of the cells under unfavourable circumstances (2) antagonistic hormones one stimulating division and the other inhibiting it (3) the age of the patient and (4) vitamin deficiency In the case of (3) and (4) there

is a shortage of factors essential for cell growth In some animals the activity of a special strain of virus might be such that invasion was often possible without the aid of such a factor or with only the irritation of the injection itself to assist (Rous sarcoma), but normally both the seed and a certain amount of specially prepared soil would be necessary

In the human body the virus is probably universally present, but normal cell division provides an insufficient susceptible phase After successful invasion the virus causes changes in the nuclear material of the cell which, as has already been pointed out, are very much akin to fertilization, and the cell then goes on rapidly growing and dividing without regard to the needs of the body, its only function being to act as host for the virus with which every cell of the growth would be infected from the start—I am, etc,

### Sterilization of Hypodermic Syringes

SIR—In the *Journal* of April 30 (p 955) there is an annotation referring to the sterilization of hypodermic syringes I would like to describe a method I have used for over thirty years, never seeing any sign of sepsis after an injection I was taught by Sir Almroth Wright to sterilize the syringe with boiling olive oil in the following way Have in a small crucible half an ounce of olive oil and a tiny crumb of bread Put a spirit lamp underneath and boil till the crumb turns brown Then fill the syringe till avoiding the crumb Do this no more than twice, or the solder holding the nozzle to the glass barrel will melt Sir Almroth Wright told me that the heat of boiling oil will kill all spores as well as germs

The next point is the use of a platinum needle, which may cost 7s 6d but with care lasts for a year When about to give an injection all that is required is to draw the needle through the spirit lamp flame The needle becomes red hot, and is then ready to suck up the vaccine or other solution I have always used a Record syringe in a metal case that takes the syringe with the needle left on When going out on a visiting round I measured my dose in the syringe, boiled a drachm of water in the metal case, poured it out, and replaced the syringe in the case It was then ready for use If by chance I touch the needle on anything it was quite easy to put in platinum needle through a flame There is no need, in my experience, to use the boiling oil in the syringe more often than once a week if the needle is kept on the nozzle There must be hundreds of men who were trained by Sir Almroth Wright in his method of syringe sterilization Why they persist in using the messy, elaborate boiling water method with steel needles passes my comprehension—I am, etc,

Birmingham, May 4

### The Phenomenon of Refection

SIR—We have read with interest the annotation upon the phenomenon of refection in your issue of April 2 (p 741)

We have worked for some ten years on this phenomenon and our latest findings embodied in a thesis by one of us (P M Kon) in 1935 and reported in the *Journal of Hygiene* (1938 38, 1), may be of interest to your readers We agree with Nathan that no specific organism can be held to be responsible for refection Further we believe that undigested starch provides the substrate for the growth of bacteria producing vitamin B But we

found that the major difference between rejected and non-rejected rats lies in a lowering of the pH of part of the intestinal tract which in the rejected animal facilitates the absorption of the vitamin B formed by the intestinal flora. The condition thus established is analogous to that normally found in the bovine and the rejected rat like the bovine is rendered independent of an exogenous supply of vitamin B.—We are etc.

### Tuberculo-protein

SIR—I was interested in the article on tuberculo protein by Dr A. T. Deig and others (*Journal* May 7 p. 992). Dr H. J. Parish of the Wellcome Physiological Research Laboratories kindly supplied me with a batch of tuberculo protein and I conducted a small investigation at the tuberculosis dispensary with it during 1957. I examined 100 patients, nearly all home contacts of tuberculous patients, varying in age from 3 months to 66 years. I injected into the skin of the right forearm 0.1 ccm of tuberculo protein and into the skin of the left forearm 0.1 ccm of 1 in 1000 old tuberculin. The results were noted either two or three days later.

In 26 patients the reactions were negative in both arms.

In 53 patients the reactions were positive and equal in both arms.

In 15 patients the reactions were positive in both arms but greater in the right (tuberculo protein).

In 8 patients the reactions were positive in both arms but greater in the left (old tuberculin).

In no case was one positive and the other negative.

When considering the inequality in reactions one should always remember the practical difficulty of injecting exactly 0.1 ccm into the skin on every occasion. As a result of this experience I came to the conclusion that for dispensary use, where considerable numbers of patients are tested and fresh supplies of old tuberculin are available tuberculo protein has no real advantage over old tuberculin. At the time I did not know of the work of Parish and O'Brien on the tenacity of tuberculin to glass and on some occasions the same syringes were used for both solutions, being washed out with surgical spirit and distilled water between each injection. Perhaps this was insufficient and because of it my results may be to some extent invalidated.—I am etc.

County Council

### The MRCP and Psychiatry

SIR—The L.C.C. Mental Hospitals Department is adopting a policy which may prove ultimately to be unwise. Medical officers in that department are now informed on their first promotion that subsequent promotion is dependent on their obtaining the MRCP. The following points should I think be considered:

1. Medical officers joining the service must obtain the DPM within three years or their appointment ceases. This is a reasonable stipulation as psychiatrists should be qualified in their special subject.

2. By specifying that MRCP is essential for promotion in addition to the DPM medical officers for a considerable time after joining the service concentrate on reading, theory examinations and attending courses. The result is that they have little time or attention for their proper duties of investigating and treating their patients and these will be neglected proportionately.

This stipulation is making the MRCP bear a significance which it is not designed to have. By forcing more and more people to take it it is becoming the qualifying examination in medicine and university degrees are being pushed into the back round.

MRCP does not necessarily make a person a better psychiatrist. Some medical subjects are intimately connected with psychiatry and these are presumably covered in the DPM course. But surely psychiatry is still the more important part of psychiatry in practice.

The work of a doctor in a mental hospital should be judged by his capacity to return patients to the community and to improve the lot of those unfit for discharge. To what extent is this aim being achieved under present conditions? Too often the M.O. looks at his patient through his stethoscope and being an MRCP is doubtless mightily interested. All honour to those of us who have laboured and been rewarded with the MRCP. But until a broader view is taken of mental illness and encouragement is given to psychiatrists who have a more comprehensive approach to the problems of mental illness many patients who might otherwise recover will continue to languish in mental hospitals.

I suggest that if higher academic degrees are wanted a psychiatric qualification—for example DPM Part 3—be arranged as a criterion of promotion in the service and notice be taken of the candidate's capacity to secure practical results by treatment of his patients. Our mental hospitals are overflowing. At present we are not doing as much as we might to get our patients well because we study their bodies more than their minds (if such a dichotomy can be allowed).—I am etc.

A.M.O.

### Treatment of Placenta Praevia

SIR—After dealing recently with a case of placenta praevia a condition which may be described as the general practitioner's bugbear I reflected as to the best course of action to be pursued in the treatment of this condition.

The patient was a primipara aged 22 and had had a normal pregnancy to within fourteen days of term. Twenty-eight days before term the head engaged satisfactorily and was in the first vertex position. Slight labour pains began at 6 p.m. one day and there was profuse bleeding. Vaginal examination showed a one finger dilatation of the cervix. On one side was felt the firm mass of a marginal placenta praevia. The membranes had ruptured and the foetal head was engaged in the pelvis. There was a steady loss of blood which increased with each successive pain. The mother's general condition was good. The foetal heart sounds were loud and at a rate of 120 a minute.

There appeared to be two alternatives—Caesarean section and conservative treatment. Caesarean section implied the danger and delay of transit (my patient was in an isolated cottage) with the additional risks of her exsanguinated condition before she reached the operating table and eventual sepsis. Conservative methods implied the awaiting of a slightly increased dilatation which would permit an internal version under general anaesthesia and plugging by the hand breech. I chose the latter course and waited until 9 p.m. There was now a two finger dilatation of the cervix. I therefore anaesthetized the patient and proceeded to dilate the cervix gradually with the first two fingers of my left hand without proceeding to an internal version. In about three quarters of an hour the cervix was sufficiently dilated to allow of the application of forceps. Free haemorrhage occurred during this interval but was not of an alarming degree. Delivery was performed very slowly since I was drawing an un moulded head through the pelvic cavity. An 8 lb live child was however eventually delivered without damage either to the cervix or to the perineum. The third stage was rapidly completed and the mother's condition though grave gave rise to no great anxiety. The foot of the bed was raised a binder applied hot bottles were placed at her feet and

pituitrin was injected. The district (Queen's) nurse who was my only assistant proved a very efficient anaesthetist and general help.

On the third day following delivery the temperature rose to 101° F and the lochia was slightly offensive. Prontosil by the mouth steadied the fever in two days, and the patient then had an uneventful puerperium being up and in good condition on the fourteenth day.

Is this method of manual dilatation of the cervix under anaesthesia followed by forceps delivery not a possible solution to the problem of treatment of placenta praevia, at least in its commonest lateral form? For all practical purposes the diagnosis of placenta praevia is by the vagina. This implies some degree of septic contamination, and it is very doubtful if Caesarean section is ever justifiable after a vaginal examination. Caesarean section is also a grave undertaking in the case of a young primipara in view of succeeding pregnancies. Turning by the internal or external methods and plugging by the half breech may save the mother but will lose the child. There does not appear to be any less risk of shock, haemorrhage and subsequent sepsis from the last-named manoeuvres than from that which I have outlined—I am, etc.,

Jersey May 5

H GORDON OLIVER

### Pasteurization of Milk

SIR—Much as I respect Dr Halliday Sutherland I regret to observe a tone of rancour in his letter in the *Journal* of May 7 (p. 1028). I hope I am wrong, as we are both trying to do a public service to the best of our ability. He infers that I am asserting without reasoning. I gladly leave that to the judgment of others. I do most certainly attach the greatest importance to milk tests for bacteria—he would be a fool who did not. But in Dr Sutherland's earlier letter and in mine we were discussing the effects of pasteurization on fertility, an entirely different proposition. I adhere to all I wrote. Tests on rats from that point of view are of very little value in respect of humans. I agree with Dr Sutherland that there are many causes for the falling birth rate—mostly economic—but careful reasoning does not convince me of any likelihood that the pasteurization of milk has an appreciable influence thereon. Milk in any form has but a small place in the adult diet. I fail to see any lack of logical deduction in the statement that a healthy nation, even if it should be slightly less fertile, is far and away a sounder proposition than a larger nation the stamina of which is undermined by a contaminated milk supply. I, in common with the vast majority of our people, will not accept Dr Sutherland's pessimistic prognostication that the nation will cease to exist if it persists in drinking pasteurized milk. I am optimistic enough to believe that Britons will like a lot of wiping out, and that pasteurization of milk will not help to that end.

I agree again with Dr Halliday Sutherland that no cow, if it be negative to the tuberculin test to-day, will be positive in three months unless it be infected in the interval. That is exactly what does happen, and was my obvious inference. The cow has been infected and the milk from that cow is sold to the public before the infection is detected as certified milk. He goes on to say 'and infection can be prevented. Will Dr Sutherland tell us how infection can be prevented with any degree of certainty?' The whole world is anxiously looking forward to the day when such a happy discovery is given to them.

Anyone can purchase what is termed 'clean' milk from almost any dairy, but that is not the point at issue.

The point is, Is that "clean" milk safe and entirely free from potential pathogenic germs? I deny that any raw milk, however clean it may be stated to be, can be guaranteed to be entirely free from active pathogenic germs unless and until it is pasteurized. The fact that 40 per cent of cows in Britain are tuberculous, as stated by Dr Sutherland, is a very conscious admission on his part that my contention that raw milk is an unsafe food (especially for children) is absolutely sound, and that pasteurization is the only scientific process at present known which can render milk safe for human consumption. Of course it can be boiled, but that is outside our discussion. It must be borne in mind that milk brought to London is conveyed for the most part in bulk and obtained from many sources—I am, etc.,

London S W 16, May 7

JAMES KIRKLAND

SIR—I notice that Dr James Kirkland, in your issue of April 30, questions the fact that certain strains of coli will survive the pasteurization process. I, in my ignorance, had imagined that this was now generally accepted, as certainly a number of bacteriologists whom I have questioned on the subject have been most emphatic, and if this was not the case, how was the coli test omitted from the qualifications of the pasteurized milk grade in the last Milk Act Amendments? Whilst admitting that the coli test may not give an accurate indication of the state of infection, I had always understood that at least if it was positive the evidence of infection was conclusive, while a negative result had not the same certainty.

To deal with Dr Kirkland's second question, it is I think, generally agreed that the process of cheese manufacture (in which a high acidity is induced in the milk) destroys the tubercle bacilli, and the argument for taking yoghurt has been that the bulgaricus and other lactic organisms have a controlling effect on the intestinal flora. I had imagined that the acidity induced in unpasteurized milk by the lactic organisms would have also had an effect in controlling the growth of pathogenic organisms of all kinds, and that therefore their growth in unpasteurized milk would have been less pronounced than in pasteurized milk once the bottle was opened in the hands of the consumer, for certainly the first step in pasteurization is the destruction of the lactic acid organisms. I have known people to say to me that they have kept pasteurized milk open for a week and still found it drinkable. Is this really in the interests of the consumer? It is for this reason that I ask for an experiment on the lines of my last letter.

In the annual report on the public health of Wiltshire, 1936, by Dr Wyndham Parker, County Medical Officer, it is stated that in 22 instances (one-third of the total number of samples) pasteurized milk supplied to schools failed if the standard applicable to the grade of 'Certified' milk is adopted—namely, that milk must not contain *B. coli* in 1/10th c.c.m. Does Dr Kirkland suggest that Dr Wyndham Parker did not take the necessary steps to see that these samples were not contaminated 'after the cap had been put on the bottle'?

Dr Kirkland also makes some statements about the use of the tuberculin test in ensuring a safe milk supply. As a T.T. milk producer of some nineteen years' standing and one who has taken an active part in tuberculosis eradication among our dairy cattle in Wiltshire, I think I may state that the only chance of improving the milk supply within three months of a saleable milk is where a closed lesion has broken down. Wiltshire

over the cattle have been regularly tested without restriction the chances of infection to an extent to endanger the milk supply at this stage are so rare as to be almost negligible. It would be as reasonable to suggest that travellers on buses or tube trains should insist that the vehicle should be disinfected every time a passenger left or a new passenger entered. Will Dr Kirkland suggest that there is no destruction of the enzymes or that he knows the full function of these in metabolism? I can only quote the case of a child suffering from toxine infection of the intestine who on pasteurized milk made no progress but rather went back. I was asked by his doctor to supply a reliable raw milk from my own farm and within three months that child was well on the way to complete recovery.

In view of the doubts which still exist in many minds both medical and lay are we entitled to insist that such a far-reaching step should be taken as to prevent the public from obtaining the milk supply which they believe to be best for themselves and for their children? I personally am convinced that much to their investigation is required—whether by a Royal Commission or other wise—so that some unanimity may be obtained and a decision may not be come to on short term tests with contradictory results whereas the full effects of diet may not show till the lapse of several generations—I am, etc.,

Rowallan Kirkwood, M.D.

ROWALLAN

\* This correspondence has now run its course and rhetorical questions can be answered elsewhere.—ED. B.M.J.

### Actinomycosis

SIR.—Will you permit me to point out that the reviewer of the monograph on *Actinomycosis* (May 7 p. 1006) thinks of me more highly than he ought to think when he suspects that the coloured drawings in the book are from the authors' own hand. Much as I would like it to be true the compliment is undeserved. Most of the coloured illustrations were done by Mr Thornton Shiells but the drawings of microscopic sections were from the hand of Miss Nicholson. I would like to take this opportunity of thanking them for their skilful work.

May I also correct an error which appears in the review where it is stated that about sixty cases in man occur in the United Kingdom annually. The fact is that about sixty persons a year die from the disease in England and Wales. This number would be from among several hundred attacked by actinomycosis—I am, etc.

### NAVAL COMPASSIONATE FUND

At the quarterly meeting of the directors of the Naval Medical Compassionate Fund held on April 22 with Surgeon Rear Admiral S. F. Dudley O.B.E., Deputy Medical Director-General of the Navy in the chair the sum of £214 was distributed among the several applicants.

## Medico-Legal

### A FATAL SWAB CASE

A surgeon and a theatre nurse were sued for negligence at Manchester Assizes on April 25 before Mr Justice Atkinson and a jury by Mrs Elizabeth Mahon the mother of Thomas Mahon aged 25 who had died as a result of toxæmia due to a swab being left in his abdomen after an operation on March 4 1937.

Mr R. P. Osborne the resident surgeon who performed the operation at the Davyhulme Park Hospital near Streatham and he had done between six hundred and even rounded abdominal operations. The patient had a perforated duodenal ulcer and an immediate operation was necessary. Nurse E. M. Ashburner the second defendant, was his theatre sister. During the operation on a note of the number of swabs being used was kept on a blackboard in the theatre. The swabs were brought in bundles of five and were checked off the theatre nurse or staff nurse before use. He had no doubt that death was due to the swab and said that she had probably been a runaway as he had been told the number of swabs was correct. It was a packing off swab 10 inches by 1 inch and his theory was that the forceps must have slipped off the tape at some time during the operation. The only other explanation was that two swabs had been given him rounded up together one with forceps on and the other without. In cross examination he agreed that it was his duty to place swabs in and take them out. He had known forceps slipping off a tape during an operation. He could not explain why he had not seen the swab if it must have been hidden from immediate view. He demonstrated the operation to the jury on a plaster model.

Miss E. M. Ashburner said she counted the swabs placed them on the operating trolley and wrote the number on the blackboard. By the time they reached the table they had been checked three times. She had checked the swabs after this operation and found them correct. Mr A. Graham Bruce visiting surgeon to the hospital who said that Mr Osborne was a first class surgeon with experience and judgment, and judicious caution liked the system of checking swabs better than any other he had used or seen. Prokes or John Morley said that he had once been saved from leaving a swab in the patient by the theatre sister who told him just before he closed the abdomen that she had miscounted. A surgeon had to balance in his judgment the harm he might do by an extensive search against the harm he might do by leaving the swab behind. In order to avoid unnecessary search the surgeon relied on the nurse's count. An extensive and prolonged search might make the difference between life and death. The system in use was carefully thought out. If the surgeon had been told the swabs were correct and had no reason in his own mind to think they were not correct, it would be wrong to make a search.

The learned judge in summing up remarked that Mr Osborne whose evidence commanded belief said he had taken out all the swabs he could see and was aware of but did not suggest that he felt round for any others. The jury found that Mr Osborne did not make a reasonably sufficient search for the swabs and that if he had the search would have disclosed the missing swab. They assessed damages at £600 and £16 funeral expenses but added a rider that Mr Osborne was working under difficult circumstances. They found that Miss Ashburner had not been negligent.

In view of the possibility of an appeal comment on this interesting case must be postponed. Nurse Ashburner had actually had judgment signed against her before the trial as she had not entered an appearance—that is she had not formally acknowledged the writ or summons—owing to a misunderstanding. The judgment against her however was set aside by consent.

## Obituary

W H MAXWELL TELLING, M D, F R C P,  
Consulting Physician General Infirmary at Leeds

Dr Maxwell Telling, honorary consulting physician to the General Infirmary at Leeds and professor of forensic medicine in the University of Leeds, died at his home on April 28 at the age of sixty-three. His health had not been good for a number of years, but, except for a few brief occasions when he was actually laid aside by illness, he had continued most of his manifold activities until within three days of his decease. A somewhat slowly developing but progressive cerebral haemorrhage was the immediate cause of death.

Walter Henry Maxwell Telling was born in Surrey (his grandfather, Thomas Henry Maxwell, was a freeman of the City of London) and educated at Camberwell

Grammar School and Guy's Hospital. He graduated M B, B S Lond in 1898 and M D (with gold medal) three years later. After holding a number of junior appointments at Guy's he came to Leeds in 1900 as resident medical officer to the General Infirmary, an institution in which he was to serve faithfully and well for the rest of his life. He was elected assistant physician in 1903, physician in 1912, and consulting physician in 1932. He was elected a Member of the

Royal College of Physicians in 1902 and a Fellow in 1913.

Telling's first formal appointment in the University of Leeds—in May, 1906—was as a clinical lecturer in medicine. Prior to that he had had charge for a few years of a section of the pathological museum, and in 1907 he became honorary demonstrator in medical pathology. In 1910 he was appointed to the newly constituted post of clinical subdean, an office which he held for three years. Becoming lecturer in pharmacology and therapeutics in 1921, he succeeded Dr H J Campbell of Bradford in the chair of therapeutics in 1923. Two years later he was promoted to the chair of medicine and headship of the department of medicine in succession to Dr Wardrop Griffith. His tenure of this office was automatically terminated seven years later by his retirement according to rule after twenty years' service on the full staff of the Infirmary. As it happened, Dr F W Eurich had just retired from the chair of forensic medicine and so in 1932, Telling was appointed in his place.

While Telling's professional career was thus mainly and inseparably bound up with these two great institutions, the General Infirmary and the University of Leeds, he had many other professional connections. He was, at the time of his death, consulting physician to St James's Hospital, the Maternity Hospital, the Women's Hospital, the Jewish Hospital and the Cookridge Convalescent Hospital. In 1905 in conjunction with the late Mr

J F Dobson, he was responsible for the development of a children's clinic in what was then the Women and Children's Hospital. Seven years later this clinic was transferred to the Infirmary, and became in due course the large and important department which it now is. The department of dermatology also owed much of its subsequent success to his tireless advocacy and stimulating encouragement in the initial stages.

As physician and clinical teacher Telling held a deservedly high position. He had been trained in the school which had carried on the traditions of Bright of Addison, of Hodgkin, and of Willis, and it is not surprising that his clinical teaching was broad based on the sure foundation of a wide and intimate knowledge of morbid anatomy. In his own words "Pathology is the breath of life to clinical medicine. Upon it we rely more and more, both for data and for inspiration." There is more solid medicine to be *understood* in the post-mortem room than in either wards or out-patients, taken separately. (*University of Leeds Med Mag* 1931, 1, 11). When the writer of this memoir joined the staff of the Leeds Infirmary in 1910, Telling was in his seventh year as assistant physician, and as such was also an honorary pathologist to the hospital, responsible for the performance of post-mortem examinations on one day a week. It was a delight to see him at work in the post-mortem room. His thoroughness, his enthusiasm, his lucid and forceful expositions were at once a revelation and an incentive to the newcomer. As a clinical teacher he excelled. Thoroughness in the investigation of cases and accuracy in the recording of findings he insisted upon, and the summaries which he was accustomed to dictate to house-physician or clerk when patients were discharged (or died) were masterpieces of succinct yet comprehensive statement. In the post-mortem room, similarly, he liked to have a "pathologist's commentary" on every case in addition to the anatomical diagnosis.

Despite his concern at one time or another with various special departments Telling remained a general physician, of the broad-minded, commonsense type. For many years he had been actively interested in psychological methods of investigation and treatment, and indeed, was a pioneer, and the chief authority in the North of England, in this field. He was in full sympathy with the Archbishop of York's movement for the development of greater co-operation between doctors and clerics in psychological matters and for the better psychological education of both professions. In the field of forensic medicine he also occupied a distinguished and authoritative position. He had an intimate knowledge of the Workmen's Compensation Act and was a skilful and experienced medical witness. In the board of medical and clinical committee of the University and in the Infirmary faculty (of which he was chairman for many years) Telling did valuable and lasting work. Many of the best features of the clinical curriculum as it exists in Leeds to-day and of the teaching arrangements in the Infirmary and hospital originated in his active and fertile brain.

In his earlier years in Leeds Telling published many accounts of interesting and unusual cases. His contributions to medical literature were marked by his own intestinal diverticulitis, fibrosis, and other conditions and psychology in relation to mind. His most considerable achievement, rightly described as a classic, was the comprehensive paper, of numerous proportions published jointly with Dr O C C

the *British Journal of Surgery* (1916-17 4 465-530) entitled "Acquired Diverticuli Diverticulitis and Peridiverticulitis of the Large Intestine".

Some of his other professional and semi-professional activities may be briefly mentioned. He was intensely interested in the training of nurses and in their welfare and as an influential member of the nursing committee of the Infirmary he was able to do much for the furtherance of his high ideals in both these directions. He was largely responsible for the present nursing curriculum in Leeds and with Professor J. Kay Jamieson for the institution of a diploma in nursing in the University. The almoner's department of the Infirmary also owed much to his sympathetic interest and support. He was much interested in massage and related subjects and was a prime mover in the establishment of a department of chiropody in the Infirmary. During the war he was divisional medical officer at the East Leeds War Hospital section of the 2nd Northern General Hospital with the rank of lieutenant colonel. A member of the British Medical Association for nearly forty years he was secretary of the Section of Medicine at the Liverpool Meeting in 1912 and vice-president of the Section of Therapeutics and Pharmacology at the Cardiff Meeting in 1928.

His interests outside medicine covered a wide field. He was actively interested in freemasonry and was a Past Master of Zetland Lodge and a foundation member of the Lodge of Living Stones. In 1927 he was appointed Sen or Grand Warden of the West Yorkshire Province. He was made a Justice of the Peace for the City of Leeds in 1917 and was an active and keenly interested member of the Bench. He was a warm supporter of the Oxford Group Movement and a vice-president of the Leeds Psychic Research Society. Always fond of music and a regular attendant at the Leeds Musical Festivals he had been a staunch supporter of the ill-fated British National Opera Company. He was passionately fond of gardens especially rock gardens and in summer his own garden overlooking Kirkstall Abbey was a joy and delight. For many years he had been a keen and discriminating collector of china especially Chinese porcelain.

Personally Telling was in truth a remarkable man. Those who came in contact with him were immediately aware that here was one possessing great force of character. When he took up a cause he threw himself wholeheartedly into the fray giving and taking shrewd blows alienating some gaining the enthusiastic support and admiration of others. He was an excellent speaker persuasive in argument cogent in reasoning lucid in exposition and when occasion demanded delightfully and sparklingly humorous. No chit was ever more willingly served or held in more affectionate regard by his housemen. His was indeed a stimulating influence and he had a faculty for getting people to give of their best. In private life he was a warm-hearted generous and loyal friend and a genial and charming host. Dr and Mrs Telling's hospitality was proverbial whether in their home in Leeds in that delightful and secluded retreat at Airton in Malhamdale to which they used to go in summer or at the opera. In his later years Dr Telling had become more than ever interested in matters spiritual and psychic. In the remarkable tribute paid to him by the Vicar of Leeds at the funeral ceremony in the parish church these words occur:

"There was a quality in the mind and spirit of Maxwell Telling by no means common. He was one of the rarer

of his kind. He was one who lived his life really within his own soul. However actively and industriously he expressed himself in work for the benefit of his fellows his real life was in his own spirit. I have known few men who are quiet for truth and for an understanding of the deeper realities of life who were more devoted and more continued."

Dr Telling married Ingeborg daughter of Julius Aagaard professor of perspective in the Royal Academy of Copenhagen and sister of Dr Otto Aagaard the distinguished urologist of that city. Mrs Telling two daughters and a son (Dr Otto Maxwell Telling) survive him.

#### G F W writes

The early and lamented death of Dr Maxwell Telling deprives Leeds of a formidable and impressive public figure. Not only was he possessed of an imposing outward appearance but he combined within himself a rare combination of remarkable zeal and diligence together with a gracious kindly and urbane nature. In the latter aspect of his character was not always immediately evident it was merely hidden by the earnestness and fervour with which he threw himself into any kind of work he found at hand. For many years he devoted himself with intense industry to the advancement of medicine in the West Riding of Yorkshire. He was a bold resolute and self-confident pioneer and he advocated many reforms which are now so much incorporated in the Leeds medical tradition that it seems incredible they could ever be the subject of controversy. Dr Telling was first and foremost an alert and learned physician but his energies overflowed freely into all kinds of activities in philosophy law art music sociology and mysticism. He was no amateur in these matters. Although he never enjoyed a complete and universal popularity yet he was rightly and proudly well aware of his commanding position in medicine. Not only did he undertake an immense consulting practice in the North of England but his opinion was eagerly sought in forensic and psychological matters and the prestige of his name was very great. In personal character he hid great kindness behind a somewhat forbidding external manner and many people looked upon him as harsh and brusque. He himself knew the whole range of human emotions and he had many triumphs and many disappointments. But in joy or sorrow he walked erect and imperturbable.

#### Dr Alexander Muirhead writes

Dr Maxwell Telling was one of those men whom our profession can ill spare. While many of our leaders were declaring that no real advance was taking place in medicine because of the lack of an undefinable something Telling came forward boldly and declared that we were being held up because we had left God out of our lives. I first met Dr Telling at a house party of the Oxford Group with which he became associated in the later years of his life. He fearlessly adopted the standards of Jesus Christ and wholeheartedly identified himself with what as a psychologist he described as "an ever increasing body of skilled and devoted workers who accomplish the healing of psychologically tangled lives in a way which comes near to the miraculous." He lost no opportunity of stressing his conviction that the true basis of health was spiritual. He was always available to "ounger" people and ready to put all the resources of his rich experience at the disposal of those whom he felt were truly serving others.

## PERCY FURNIVALL, F.R.C.S.

Consulting Surgeon to the London Hospital

Percy Furnivall who died on May 3, aged 70, received his medical education at St Bartholomew's Hospital, qualifying in 1892. After holding house appointments he took the Fellowship of the Royal College of Surgeons of England in 1895, and in 1898 was awarded the Jacksonian Prize of the College, an honour of which he was always very proud. He was next elected assistant surgeon to St Mark's Hospital for Diseases of the Rectum, and in 1899 a vacancy for assistant surgeon occurring at the

London Hospital, he applied for and was elected to this post. His coming to the

London was not too well received either by the honorary staff or by the students of the hospital, as there was in the field a strong candidate in a well-liked "Londoner," but the coldness of his reception was soon swept away by his geniality and friendliness. Furnivall rapidly identified himself with all the activities of his new hospital, and any idea that he was an "outsider" was quickly lost, and

the London Hospital never had a better or more loyal stepson. An athlete himself, as a young man he was an English amateur cycling champion. He took a keen interest in the students' sports, and was one of the first to identify himself with all the activities of the recently formed Students' Club Union. It was also largely due to his efforts that the London Hospital Masonic Lodge was inaugurated.

As a surgeon he was accurate in diagnosis, bold in his conception of treatment, and fearless in carrying it out, but at the same time was a careful and safe operator. To his patients he was always kind and cheery and optimistic, and to the nursing staff invariably courteous and considerate. As a teacher Furnivall did not hold any post in the Medical College but his clinical teaching in the out-patient department, in the wards and operating theatre, was excellent and much appreciated by the students. As might be expected of a Hunterian Professor of Pathology, he laid great stress on this subject, and grounded his opinions and his treatment on a firm pathological basis, and in the many articles he wrote this subject was always prominent. One of the traits that endeared him to the resident staff and to his junior colleagues as he rose in the hospital service, was his unselfishness and his readiness to help the younger generation both in the hospital and when they were seeking appointments elsewhere. His house surgeons were given plenty of work to do within their capacity, but such work was not given indiscriminately for Furnivall was a shrewd judge of character and ability. A house-surgeon who did not reach a high standard was quickly shown that better work was expected of him before the full benefits of the appointment were allowed him but if this standard was reached every chance and encouragement was given to a man to improve his knowledge and surgical skill.

Furnivall's geniality was almost a by-word with his colleagues and his personality was always exerted for peace in those little frictions that always occur when a

large body of men are working together. Never really a robust man, suffering always from insomnia and affected by the cold, Furnivall was frequently laid up with coughs and influenza, and finding his health deteriorating in London he resigned his appointment as surgeon to the hospital, and was at once elected a consulting surgeon in 1919. The whole hospital deplored the loss of a colleague and of a friend—the "stranger" of 1899 had become the personal friend of all in 1919, and he retired to the milder climate of Cornwall, carrying with him the good wishes of everyone who knew him. Furnivall continued to do some consulting work in the neighbouring country, and any "Londoner" visiting him was always sure of a warm welcome and a kindly store of reminiscences and stories.

The essential kindness of Percy Furnivall and his love of humanity (writes a colleague) were perhaps best shown in the publication of a diary of his experiences when suffering from the malignant disease which caused his death, and its treatment. This account, so pathetic as it is, especially to those who knew him, was not written to gain sympathy or notoriety, nor in any spirit of bravado, nor with any idea of scientific research or record, but solely with the idea of benefiting his fellow men. Rightly or wrongly, he formed the opinion that the treatment he had undergone had increased his suffering and made his passing more difficult, and he wished in his love for humanity to save others from a like fate. No medical man could read that diary unmoved, whether he agrees with its conclusions or not, but to those of us who knew him it is unspeakably pathetic, for Furnivall always enjoyed life in all its aspects. To his work and to his play he gave all that was in him and enjoyed the giving and for him to write of his life, "Is it worth while?" showed the extent of his sufferings, although, as the diary reveals, he bore them with fortitude and even with hope. But even towards the end, still in pain and distress, with little hope left in life except continual pain, Percy Furnivall's medical judgment and outlook remained sane and sound. He did not condemn the modern treatment of malignant disease, he did not curse radium and turn his face to the wall and die, but asked for generous support for a continued intensive research into the effects of radium on the tissues and a careful consideration of all the factors of a case before deciding on its use. He felt as he taught in the years gone by that pathological facts are a more sure basis for treatment than indiscriminate experiments on human beings. He asked for this research with the hope not only that others might escape his sufferings but that they might possibly be cured of the scourge of malignant disease. He only wished that the members of the profession he had served so well would be careful in the use of a remedy powerful in benefit but equally powerful to make the remedy worse than the disease.

Mr H. S. Souttar writes

It is difficult to realize that Percy Furnivall has been. Indeed, it is difficult to think of him as anything but a man in the fullest prime of life, bursting with energy. I was a dresser to the firm of Eve and Furnivall in 1904 and I still see the tall gaunt figure in a great turban smoking an enormous cigar, stepping out from one of the earliest of motor cars and striding into the house. Even then he was a figure of romance, and strange stories were told of how he had bicycled up to Cambridge in the morning, won an open mile bicycle race in the afternoon and cycled back to London in the evening. He was

his dressers as younger brothers and though his technique was entirely unconventional it was full of sound common sense and admirable surgical judgment. His skill as an operator was quite exceptional and there still remains in my memory his intense passion for asepsis. It was before the days of gloves and after we had scrubbed up he would insist on snipping off a small portion of a nail from each dresser as well as from his own hand, all to be carefully cultured. The surgery of today has been reduced to an established routine and surgeons themselves have become conventional but it is pleasant to remember and to do honour to those who struck out boldly into a new and unknown field and among them for those who knew him few could be remembered with higher regard and deeper affection than Percy Furnivall.

#### I. L. PROVIS, F.R.C.S. ED

Mr Francis Lionel Provis, who was well known for his work in the application of radiology to gynaecological practice, died on May 2 at the age of 68. The youngest son of the late Dr Wilton Provis of Mere, Wiltshire, he was educated at Bromsgrove School and St Bartholomew's Hospital and in 1895 obtained the English Conjoint diploma. He became M.R.C.P. Ed in 1903, having been admitted a Fellow of the Royal College of Surgeons of Edinburgh in the previous year. He held the house appointment of resident medical officer at the Tottenham Hospital and was medical registrar at the Chelsea Hospital for Women. During the South African War he was on the staff of Lady Curzon's hospital unit and was assistant physician to the Imperial Yeomanry Hospital at Pretoria. After the war he decided to devote himself to the study and practice of gynaecology. He was elected surgeon to the Chelsea Hospital for Women and gynaecologist to the Fabian Hospital; he was also surgeon accoucheur to the St Pancras Dispensary and later to St John's Hospital, Twickenham. He was for some time medical officer in charge of the venereal department of the Prince of Wales General Hospital. Mr Provis contributed various papers on gynaecological and radiological subjects to medical periodicals and became widely known in connexion with modern gynaecological treatment and also with the research work relating to therapeutics of venereal disease. His sturdy independent outlook combined with scientific acumen and great clinical abilities rendered him prominent in his specialty and he built up a large consulting practice in Harley Street.

#### Mr Victor Bonney writes

All those who are connected with Chelsea Hospital for Women will mourn the passing of Lionel Provis. He joined the hospital as registrar in 1902, became a member of the honorary staff in 1903 and for twenty-seven years did his utmost for it. He was early interested in the application of radiology to gynaecology and is justly to be considered as one of the pioneers in that subject. He was a careful and conscientious surgeon and a gentle and humane man with a high sense of the responsibility he owed to his patients. His health broke down and compelled him to resign from the staff in 1931 but he did not entirely disavow himself from his work and indeed continued it so far as he was able almost to the time of his death. He will be best remembered by those who had the privilege of working with him for his kindness of heart, his honesty, his contempt of everything savouring of jealousy or meanness and most of all for the uncompromising courage with which he bore his misfortunes.

#### EDMUND WILKINSON, F.R.C.S.

Lieutenant Colonel I.M.S. (ret.)

Lieutenant Colonel Edmund Wilkinson died suddenly at his residence, Hornacott Manor near Launceston, Cornwall, on May 1. Born in 1867, he received his medical education at University College and University College Hospital. He qualified as M.R.C.S. and L.R.C.P. in 1888 and after holding hospital appointments took the F.R.C.S. in 1892. In the Indian Medical Service he had a distinguished career as an epidemiologist and an authority on plague. He was Chief Plague Medical Officer and Sanitary Commissioner in the Punjab and Acting Sanitary Commissioner for East Bengal and Assam. He retired at the end of his period of service with the rank of lieutenant colonel.

#### Sir Arthur MacNalty writes

To a man of Wilkinson's energetic disposition and capacity for work a life of ease at home offered no attractions and we were glad to welcome him as a medical inspector when he joined us at the Local Government Board in 1914. Here his plague experience proved invaluable not only in port sanitary work but also in connexion with precautions against the spread of that disease in East Anglia. During the war he rendered great service in promoting and securing liaison between the military authorities and the local authorities in the sanitary services for military camps and hospitals. Wilkinson could appreciate both the military and the civilian aspects of these problems and was able to reconcile interests which at times appeared to be conflicting. After the war as a medical officer of the Ministry of Health his time was chiefly occupied in port work and in the investigation of epidemic outbreaks.

Wilkinson retired from the Ministry in 1932. He went to live in his native county, Cornwall, where he was fully occupied in the administration of his estate and in many local activities. He was a good shot, a keen fisherman and an ardent motorist whilst at any time he could spare from his many occupations was devoted to colour photography. At Hornacott Manor Colonel and Mrs. Wilkinson were always delighted to welcome old colleagues and several of us have grateful memories of their kind hospitality. Wilkinson's life was a full one crowded with successful work and good deeds. One could never imagine him growing old. He has died as he would have wished without any premonitory change in his mental and physical powers.

#### A. W. NEILL, M.D.

Dr Alexander William Neill, whose death occurred on May 2 at Oxford at the age of 58, had been physician superintendent of the Warneford Mental Hospital, Oxford, since 1914. Dr Neill was educated at George Watson's College, Edinburgh, and Edinburgh University. He graduated M.B. Ch.B. in 1903 and proceeded to the degree of M.D. in 1911. After holding resident posts in the Royal Infirmary, Edinburgh, Woodburn Sanatorium and West Bromwich Hospital, he became senior assistant physician at the Royal Asylum, Edinburgh. He was an ex-president of the Royal Medical Society of Edinburgh. Dr Neill was a member of the British Medical Association for nearly twenty years. He was secretary of the Oxford Division in 1922-3 and chairman in the following year. When the Association met at Oxford in 1936 he was responsible for the local arrangements in connexion with the Reception Room and Exhibition. In 1932 he served as president of the Oxford Caledonian Society. Dr Neill

in his younger days took part in many forms of sport, being especially proficient at hockey and curling. He leaves a widow and two sons, the elder of whom is studying medicine.

Mr J F Robinson, FRCS, writes

In the passing of Dr Alexander Neill the profession in Oxford has lost a loyal and helpful colleague, and the Warneford Mental Hospital a very capable and just administrator. Besides his purely professional work at the hospital and his consultative work in the neighbourhood, he had a real genius for organization. The committee of the Warneford Hospital must be grateful for his wise direction and co-operation in the numerous schemes which he initiated to put the hospital on a sound foundation for the future. But it is not his achievements in this direction that I wish to emphasize. I leave that for others more fitted to describe and appreciate. To me the death of Neill is a personal loss. I knew him soon after he came to Oxford, and have been intimate with him ever since. His hospitality was lavish, and many medical men in this district will remember the jolly evenings we had at the Warneford right up to the time of his illness. He will be missed at the Medical Club (as distinct from the Oxford Medical Society), where his contributions to the discussions often brought us down from the unsubstantial clouds to solid earth. His kindness, loyalty, and common sense were his outstanding characteristics. I have often been to him for advice on divers occasions, and his broad view of things and man-of-the-world (in the best sense) outlook were of great value to me. He certainly had his share of trouble during recent years, but he was very reticent, and few would know what he suffered. His long recent illness was borne with the cheerful courage that was expected of him.

Dr CYRIL PATRICK ANDREW STRANAGHAN who practised for several years at Folkestone and Bournemouth, died on April 19. He retired from general practice nearly two years ago. A graduate of Edinburgh University, where he was an enthusiastic Rugby football player, he was later appointed house-physician at the Royal Infirmary, Sunderland. During the great war he served in France with distinction. He was a man of great personal charm and wide human sympathy which, apart from his sound professional skill, endeared him to colleagues and patients alike. His brief period of retirement only helped to strengthen the deep affection in which he was universally held.

EVAN WILLIAMS RICHARDS M B Ed, Ch B, DPH Glasg, died at his home in Newtown, Montgomeryshire, on February 23. He was for eleven years medical officer of health and schools medical officer for Montgomeryshire, and previously held a similar appointment for the borough of Port Talbot in Glamorgan. He had been a member of the Shropshire and Mid-Wales Branch of the British Medical Association for the past twenty-five years. Dr Ivor J Davies, physician to the Cardiff Royal Infirmary, writes: Dr Richards took his degrees at Edinburgh in 1910 and acted as house-surgeon at the Cardiff Royal Infirmary for twelve months, and afterwards was in colliery practice at Abertridwr for three years, where he was much esteemed for his skill and lovable personality. He was one of the first of a brave band of general practitioners to assist in the rescue work at Senghennydd, where the worst explosion in the history of the coal industry occurred in 1913. I can well remember Richards's fine bearing just as he was about to descend the mine with a rescue brigade. He served throughout the war at the 3rd Western General Hospital, RAMC (T), from the time of its establishment on the outbreak of war in 1914 to its closure in 1919. He was one of the best house-men

the Royal Infirmary has ever had, and his war work was characterized by the same thoroughness and devotion to duty. Owing to an old disability Richards was unable to serve abroad, but he never spared himself in the work of a large territorial hospital, and was always ready to undertake extra work for a colleague. He will best be remembered for his fine temperament and sterling gifts of character, and was such as we would all wish to be: gentle in manner, patient in all his dealings yet unbending in what he believed to be right and true, and steadfast in faith. Those of us who were privileged to be his friends will always be inspired by the nobility of his character.
